ABSTRACT: There is an urgent need for accessible purification and separation strategies of atomically precise metal clusters in order to promote the study their fundamental properties. Although the separation of mixtures of atomically precise gold clusters Au25Lm, where L are thiolates, has been demonstrated by advanced separation techniques, we present here the first separation of metal clusters by thin layer chromatography (TLC), which is simple yet surprisingly efficient. This method was successfully applied to a mixture of Au25Lm with different ligands, as well as to a binary mixture of different cluster cores, Au135 and Au144, protected with the same ligand. Importantly, TLC even enabled the challenging separation of a multi-component mixture of mixed-monolayer-protected Au25 clusters with closely similar chemical ligand compositions. We anticipate that the realization of such simple yet efficient separation technique will progress the detailed investigation of cluster properties.

INTRODUCTION

Atomically precise clusters of noble metals protected with monolayers are some of the most fascinating molecules of contemporary chemical science.1-3 Most of the reports on such clusters are concerned with gold but a few analogues of silver and copper have also appeared in the literature.4-10 Molecules such as Au135SR4,11-13 Au135SR4×14 and Au144SR6×15 are some of the most stable species in this family of materials. Catalytic and biological applications of such materials are fast evolving.16-18 Along with this development, we have begun to explore the complex chemistry of these systems.19-21 The different chemically non-equivalent environments at their surfaces offer different possibilities for ligand exchange. Possibility of core rearrangement, reduction in size and chirality of the core contribute to the diversity of their chemistry.21-23 Whereas some synthesis protocols may produce directly atomically precise metal clusters without the need for separation, other synthesis protocols always yield a mixture of slightly different atomically precise metal clusters and their separation often is a challenge.24-26 Efficient methods to isolate the chemically varying species would enhance the growth of science in this area. In this article, we present a simple yet effective way of separating atomically precise clusters, which helps to expand the exploration of their diverse properties.

Although high pressure liquid chromatography (HPLC),27-28 polyacrylamide gel electrophoresis (PAGE)24,25 and solvent extraction are used extensively in separating clusters,29-31 the simplest of chromatographic techniques, namely, thin layer chromatography (TLC) has not been attempted for the separation of such clusters. In the following, we show that differently functionalized clusters of the same core, varying cores with the same chemical functionality and even mixed-monolayer-protected clusters of the same core having only slight structural differences are well separable by a simple TLC methodology. Even though TLC has been used in organic chemistry for a long time, the realization of its applicability to metal clusters adds a new tool in the toolbox of cluster science and further emphasizes the analogous nature of metal clusters and small organic molecules.

EXPERIMENTAL SECTION

Chemicals and Materials. Gold(III) chloride trihydrate (≥ 99.9 %), butanethiol (99 %), hexanethiol (99 %), phenylethanol-thiol (≥ 99 %), sodium borohydride (95 %), tetraoctylammonium bromide (TOABr, 98 %) and trans-2-[3-(4-tert-butylphenyl)-2-methyl-2-propenylidene]malononitrile (DCTB, > 98 %) were purchased from Sigma-Aldrich. Tetrathiolated calix[4]arene (25,26,27,28-tetrakis(4-mercapto- n-butoxy)calix[4]arene) was synthesized according to a reported method.32 All the chemicals were used as received without further purification. All solvents (dichloromethane (DCM), hexane, tetrahydrofuran (THF) and methanol) were purchased from Sigma or Rankem and were of analytical grade. Silica gel 60 F254 TLC plates were purchased from Merck. The water used in syntheses was Milli-Q grade with a resistivity of 18.2 MΩ-cm.
Synthesis of Au25L18 and Mixed Monolayer Au25Calix6-BT18 Clusters. Au25BT18 \( (\text{BT- butane thiolate, C}_6\text{H}_3\text{S}) \) and the calixarene-functionalized Au25 clusters were synthesized by a reported method. Briefly, HAuCl₄ \( \cdot 3 \text{H}_2\text{O} (80 \text{ mg}) \) was dissolved in 15 ml THF and 130 mg of TOABr was added to this vigorously stirred solution. The stirring was continued for 15 min after which the solution was orange-red in color. To this solution, 110 µl butanethioll in 500 µl THF (in case of Au25BT18) or a mixture of 110 µl butanethiol and 4.4 mg of calixarene tetraethiol in 500 µl THF (in case of Au25Calix6-BT18) was rapidly added under vigorous stirring (1200 RPM). The stirring was continued for 2 h during which the solution turned colorless. After that, 78 mg NaBH₄ dissolved in 5 ml ice-cold H₂O was rapidly added to the reaction solution under vigorous stirring and the stirring was continued for 5 h in case of Au25BT18 and 15 h in case of Au25Calix6-BT18. The solvent was removed from the reaction mixture by rotary vacuum evaporation and clusters were purified by centrifugal washing with methanol (4 times, 3000 RCF). In the case of Au25BT18, methanol:water mixture (3:1 v/v) was used in centrifugal washing. Subsequently, the product was washed to THF and the white insoluble matter consisting most likely of Au(I)-thiolates was removed by centrifugation. In case of Au25Calix6-BT18, the clusters in THF were further purified by size-exclusion chromatography (stationary phase Bio-Rad BioBeads S-X1 200-400 Mesh) to remove a small amount of larger clusters. Au25PET18 (PET- phenylethane thiolate, PhCH₂CH₂S-) and Au25HT18 (HT- hexane thiolate, C₆H₁₃S-) were synthesized following the same procedure. 136 µl and 144 µl thiol were added for the synthesis of Au25PET18 and Au25HT18, respectively.

Synthesis of Au25PET18 and Au14PET60 Mixture. Au25PET18 and Au14PET60 were synthesized according to a reported method. HAuCl₄ \( \cdot 3 \text{H}_2\text{O} (120 \text{ mg}) \) was dissolved in 15 ml methanol and 193 mg of TOAB dissolved in 15 ml methanol was rapidly added to this vigorously stirred solution. The stirring was continued for 15 min after which the solution was orange-red in color. To this solution, 216 µl phenylethanolthiol was added and the mixture was stirred for 15 min. After that, 115 mg NaBH₄ dissolved in 6 ml ice-cold H₂O was rapidly added to the reaction mixture. The stirring was continued for 5 h at room temperature, after which the precipitated clusters were collected centrifugation and washed with methanol 5 times. The clusters (Au25PET18 and Au14PET60) were dissolved in DCM and precipitate consisting of insoluble Au-thiolates was removed. DCM solution was rotary evaporated to dryness and spotted on the TLC plate for separation.

TLC Separation. The cluster samples (1 µl) were pipetted to TLC plates and dried in air. After drying, the plate was eluted with DCM/hexane mixture (the optimal solvent mixture varies with cluster system). After the separation, the bands were cut from the TLC plate and the clusters from each band were individually extracted with DCM. The solids (pieces of TLC plate) were removed from these extracts by centrifugation. The retention factors \( R_f \) for all separated clusters are given in the Supporting Information (Table S-1).

Characterization. Absorption spectra of clusters were recorded in UV–visible range with PerkinElmer Lambda 25 UV-vis absorption spectrophotometer. Clusters were dissolved to DCM and spectra recorded in quartz cells with 10 mm path length. Matrix-assisted laser desorption ionization (MALDI) mass spectra of clusters were collected using either of two different linear time-of-flight mass spectrometers: Voyager DE PRO (Applied Biosystems) or Autoflex II (Bruker Daltoniks). Both mass spectrometers were equipped with UV/N2-lasers (337 nm) and provided similar results. DCTB in DCM (12.5 mg/ml) was used as the matrix. The measurements were performed in positive ion mode. For each measurement, typically 500 scans were acquired.

RESULTS AND DISCUSSION

Separation of Binary Mixture of Au25L18, \( L = \text{BT / HT / PET} \). In Figure 1 we show the separation of Au25HT18 (HT-hexane thiolate, C₆H₁₃S-) and Au25BT18 (BT- butane thiolate, C₆H₃S-) from a mixture of two, though the polarity difference of BT and HT is very small. Mixture of clusters was spotted on the TLC plate and then eluted using DCM/hexane mixture. For this system, the best separation occurred at a DCM/hexane ratio of 40:60 (unless otherwise noted, the solvent ratios are expressed as volume ratios throughout the manuscript). Photograph of the two separated bands is shown in Figure 1A. After optimization of the solvent mixture, preparative scale separation was performed by simultaneously eluting multiple spots of this mixture. The separated bands 1 and 2 were cut off from the plate and individually extracted using DCM. The UV-vis spectra of band 1 (red) and band 2 (blue) show characteristic absorption features originating from the Au25 core (Figure 1).

![Figure 1](image)
BT and PET protected Au_{25} using the same methodology. Both the clusters were spotted on the same

Figure 2. A) UV-vis spectra of the two bands separated by TLC. Red trace matches well with the previously reported UV-vis spectrum of Au_{144}PET_{60} cluster\textsuperscript{15} and blue trace matches with the UV-vis spectrum of Au_{25}PET_{18} cluster.\textsuperscript{15} The red trace has been vertically shifted for clarity. Inset: Photograph of the TLC plate used for cluster separation (solvent front marked as a dashed line). B) MALDI MS data of crude (black trace) and isolated clusters (blue and red trace) confirming that bands 1 and 2 consist of isolated Au_{25}PET_{18} and Au_{144}PET_{60}, respectively. The fragmented product, Au_{21}L_{14} is shown with an asterisk (*).

Analogously to TLC separation of small organic molecules, the choice of solvent polarity plays a key role in deciding the extent of separation of clusters. In 100% DCM, all the Au_{25} clusters elute along with the solvent front and thus no separation occurred in either BT-HT or BT-PET system. In both systems, slight decrease of solvent polarity reduces the movement of clusters on the TLC plate resulting in a clear separation of the two bands. For the BT-HT system, we have decreased the polarity of the solvent mixture more than that used in the BT-PET system. In the former case the movement of clusters on the TLC plate should be slow to get a better separation as the polarity difference between BT and HT is very small in comparison to BT-PET system.

It is worth noting that, based on the UV-vis spectra in Figure 1, the charge of the separated clusters is neutral. Au_{25}L_{18} clusters have two significantly stable oxidation states, namely Au_{25}L_{18}^- and Au_{25}L_{18}^0 which can be converted from one to another by electrochemistry\textsuperscript{34} and by exposure to oxidizing or reducing agents.\textsuperscript{35} Fresh Au_{25}L_{18} synthesis products are typically negative charged. However, these clusters easily oxidize to Au_{25}L_{18}^0 due to exposure to air and ambient light.\textsuperscript{36,37} When separating freshly prepared Au_{25}PET_{18} by TLC, we observed a rapid oxidation during drying and elution of the clusters on the TLC plate (Figure S-2). If drying and elution times are decreased, thus leading to only partial oxidation, even separation of Au_{25}L_{18}^- and Au_{25}L_{18}^0 can be realized with TLC, since Au_{25}L_{18}^- elutes slower than Au_{25}L_{18}^0 likely due to the attached TOA\textsuperscript{+} (Figure S-3).
Figure 3. MALDI MS data of Au$_{25}$Calix$_0$BT$_{6-18}$ cluster mixture. Peak spacings of 773 m/z (1 Calix) and 178.4 m/z (2 BT) have been marked for clarity. The compositions of the labelled peaks (1-13) are interpreted in Table S-2. Insets show the structures of the ligands in the mixed-monolayer-protected Au$_{25}$ clusters.

Figure 4. A) Photograph of the TLC plate used for cluster separation. The faint bands observed between bands 1 and 2 are caused by sticking of the clusters to the TLC plate upon drying between runs (Note that the TLC plates were eluted repeatedly. See also supporting information, Figure S-4). B) MALDI MS data of Au$_{25}$Calix$_0$BT$_{6-18}$ crude product before TLC (black trace) and bands 1-5 separated by TLC. The mixture contains both Au$_{25}$PET$_{18}$ and Au$_{144}$PET$_{60}$ (Figure 2B). As ionization efficiency of Au$_{25}$ is considerably higher than that of the bigger cluster Au$_{144}$, the intensity of MALDI MS peak for the former is higher. Expanded spectrum shows the presence of Au$_{144}$. Blue and red traces confirm that bands 1 and 2 contain pure Au$_{25}$ and Au$_{144}$, respectively. Due to its reduced size, Au$_{25}$ elutes faster on the TLC plate. As differently sized clusters can be separated by TLC, we foresee this method to be applicable in monitoring cluster synthesis (see further discussion below).

Separation of Mixed-Monolayer-Protected Clusters. To further explore the potential of TLC separation, we continued our study with mixed-monolayer-protected Au$_{25}$ clusters, in which the monolayer consisted of BT and tetrathiolate of 25,26,27,28-tetrakis (4-mercapto-n-butoxy)calix[4]arene (Ca-lix, Figure 3 inset). MALDI MS measurements confirmed that the clusters contained 0−3 calixarene moieties (Figure 3), which is in agreement with our earlier electrospray ionization mass spectrometric study.$^{32}$ The MALDI MS data shows that the crude product is composed of several different clusters varying slightly in their monolayer composition (Au$_{25}$Calix$_0$BT$_{6-18}$).

Notably, the tetrathiolated Calix ligands are bound to Au$_{25}$ surface predominantly in tetradentate or bidentate manner leading to the absence of odd numbers of BT ligands on the clusters. Peak positions and molecular compositions are discussed in supporting information (Table S-2 and S-3). This cluster mixture was subjected to TLC with DCM/hexane mixture as the eluent. For this system, the optimal DCM/hexane ratio was found to be 30:70. Even though the clusters elute more slowly in such low polarity media, we observed undesired smearing of bands with higher DCM content. In order to achieve a greater separation between the bands, the same TLC plate was eluted several times. Four distinct bands could be separated in this manner, in addition to the immobile base band (Figure 4A). To confirm the identity of these bands, they were extracted and analyzed by MALDI MS using DCTB as the matrix (Figure 4B).

From the MALDI MS data of bands 1-5, it is evident that the fastest eluting clusters are Au$_{25}$BT$_{18}$ (band 1, blue) followed by Au$_{25}$Calix$_0$BT$_{16}$ (band 2, green) and Au$_{25}$Calix$_0$BT$_{14}$ (band 3, magenta). Surprisingly, even clusters having such minor differences in composition could be separated by TLC. Au$_{25}$Calix$_0$BT$_{16}$ is less polar than Au$_{25}$Calix$_0$BT$_{14}$ based on the difference in conformation and binding of Calix on cluster surface and therefore it elutes faster (see further discussion below). Furthermore, band 4 is composed of clusters having exclusively 2 Calix moieties (Au$_{25}$Calix$_2$BT$_{10-16}$) whereas the majority of clusters in the immobile base band 5 have 3 Calix units attached. It is worth to mention that no separation of Au$_{25}$Calix$_0$BT$_{6-18}$ clusters could be achieved by size-exclusion chromatography.
Visible light

UV light

Figure 6. Photographs of TLC separation of small amount of thiol present in methanol-washed Au₅₋₁₈ clusters. A) and B) are the photographs of same TLC plate under visible and UV light, respectively.

We have also shown that it is possible to monitor the progress of cluster synthesis by TLC. In supporting information (Figure S-5) we have presented the time-dependent TLC of synthesis of Au₂ NotificationCenter[s]. In this experiment, aliquots of the raw cluster mixture were precipitated by addition of water and further washed with methanol to quickly remove most of the excess thiol. Thereafter, the clusters were spotted to a TLC plate and eluted with hexane to completely remove the remaining thiol. Subsequently, the clusters were eluted with DCM/hexane 60:40.

Initially, a mixture of clusters is formed as shown in Figure S-5A after 1 h and 3 h of reaction. The fraction of larger clusters decreases as the reaction proceeds and after 8 h, TLC of the sample shows a single band (Figure S-5A, right). It implies that the synthesis of Au₅₋₁₈ was completed after 8 h. The bands after 1 h of reaction were individually extracted with DCM and further purified by another TLC run. The bands were analyzed by MALDI MS (Figure S-5B). The data shows that top band (band 1) consists of Au₅₋₁₈ clusters, as expected. Slightly below the Au₅₋₁₈ band, we observed a band mainly composed of Au₁₀₋₁₈ and Au₁₄₋₁₈ clusters. Moreover, bands 3 and 4 were found to contain multiple larger clusters in the size range of 12000–15000 m/z and 14000–21000 m/z, respectively. In addition, band 3 produced a strong MALDI MS signal of Au₂₁₋₂₅ cluster. This experiment further validates that clusters of different nuclearities can be separated by TLC. We foresee TLC as a highly applicable tool in monitoring cluster synthesis that advances the understanding of reaction pathways leading to specific clusters and provides a straightforward way for optimization of synthetic methods.

CONCLUSIONS

In summary, we have shown the surprisingly efficient TLC separation of atomically precise clusters of gold varying in ligand structure, core size and mixed-monolayer composition. The data presented show that simple, inexpensive chromatographic tools can be used for the isolation of monolayer-protected clusters although they are chemically complex. We anticipate that such a simple, broadly applicable methodology will enhance the detailed investigation and understanding of
chemical and photophysical properties of well-defined cluster systems.
