From Mind to Products: Towards Social Manufacturing and Service

Gang Xiong, *Senior Member, IEEE*, Fei-Yue Wang, *Fellow, IEEE*, Timo R. Nyberg, Xiuqin Shang, Mengchu Zhou, *Fellow, IEEE*, Zhen Shen, Shuangshuang Li, and Chao Guo

Abstract—After reviewing the development of industrial manufacturing, a novel concept called social manufacturing (SM) and service are proposed as an innovative manufacturing solution for the coming personalized customization era. SM can realize a customer's requirements of “from mind to products”, and fulfill tangible and intangible needs of a prosumer, i.e., producer and consumer at the same time. It represents a manufacturing trend, and is expected to become popular in more and more industries. First, a comparison between mass customization and SM is given out, and the basis and motivation from social network to SM is analyzed. Then, its basic theories and supporting technologies, like Internet of Things (IoT), social networks, cloud computing, 3D printing, and intelligent systems, are introduced and analyzed, and an SM platform prototype is developed. Finally, three transformation modes towards SM and 3D printing are suggested for different user cases.

Index Terms—Big data, cloud computing, intelligent system, social manufacturing, social networks, 3D printing.

I. INTRODUCTION

BEFORE 1760s, many wanted products could not be made out at all; some domestic articles like clothing, shoes and knives, were made by producers one by one at either home or private workshop manually or with simple tools, for themselves or customers nearby, which was named as a craft production (CP) mode. The first industrial revolution

started from UK in the 17th century. The new equipment like steamers and other machinery led to a mechanical Mass Production (MP) mode. Scarce products like carriages were made in public factories by producers for more customers; the second industrial revolution happened during 1870s-1980s, internal combustion engine, electrical devices and production lines led to an electrical MP mode. Mass products like cars and airplanes were made by manufacturers in mass factories to fulfill the customers' common requirements; a MP mode is suitable for standardized products in big quantities. It represented a main stream before 1980s. The third industrial revolution happened during 1980s-2010s, the new tools like electrics, automatic devices and production lines, and manufacturing management systems led to a mass customization (MC) mode [1]–[5], where mass customized products like shoes and clothes are designed and made by the networked factories to fulfill the different product needs of different customers. The MC mode is suitable for mass customized products or services. It has been adopted by more and more industries to meet mass customer-specific requirements since 1980s. The development history of industrial manufacturing can be summarized as Fig. 1.

The demand and supply relationship for a single customer under different manufacturing modes of CP, MP, MC and SM is shown in Fig. 2. If the supply volume approximates the demand volume, it means that the supply can meet the demand; otherwise supply cannot meet the demand. Take clothing industry as an example, CP could not make enough clothing to meet customers' needs. MP could make enough clothing to meet their common and material need, but could not meet their customized or spiritual needs. MC could make enough clothing to meet the predefined material and spiritual needs, but still could not meet their personalized and spiritual needs completely. For personal consumption articles like clothing, their spiritual needs like suiting the fashion become more important than their material needs like body protection and keeping warm. The newly emerging SM, however, promises to enable to satisfy their personal needs completely.

This paper is organized as follows: Section I retrospect the manufacturing history. Section II presents the state of manufacturing industry and describes the need for SM and service in both demand and technical aspects. Section III introduces the basic theory, key technologies and system platform of SM. Section IV proposes three types of SM modes. Section V concludes this paper and gives future work.

II. SOCIAL MANUFACTURING AND SERVICE

In 1990s, shortage of light industries in various degrees was experienced in the global market, especially in the developing countries market. Customers outnumbered the amount of products the manufactures could make. Those manufacturers in developing countries, like China and Mexico, started to win the marketing competitiveness in middle and low-end products, because they could apply the MP mode to make much cheaper mass products with lower labor, R&D, material and production cost and looser environment protection regulation. The manufacturers in the developed countries and regions had to transform into MC mode to keep their marketing competitiveness in high-end products. From 2010, product surplus appeared in the global market. In other words, global manufacturers made more products than customers could buy and consume. MP and MC migrated to those new region, e.g.,

Vietnam and African countries. So, a novel production mode should be created for those manufacturers in developed and some previous developing countries like China.

Since 2010s, cyber-physical system (CPS), cyber-physical social system (CPSS) and Industry 4.0/5.0 have emerged and become hot research and industrial practice topics [6]–[9]. In manufacturing industry, the latest supporting technologies like Internet of Things (IoT), social networks, cloud computing, 3D Printing, and knowledge based intelligent systems, led to an innovative SM mode [10]–[14], where physical manufacturing facility, capacity and social factors are reflected into a manufacturing cyber space. There appears a new concept called a “prosumer”, a person who consumes and produces a product and service [15], [16]. It is derived from “prosumption”, a dot-com era business term meaning “production by consumers”. These terms were coined by American futurist Alvin Toffler [17], and were widely used by many technology writers of

the time. Every prosumer can design the personalized products like apparel, shoes, or portraiture online for his/her own need with some way like game playing. A personalized product can be made by pressing a “MAKE” button while the actual “making” requires intelligent SM facilities like cloud based virtual factories and the networked 3D printers. It is likely that 3D printing and SM together represent a new wave of industrial revolution.

In an SM era, the coordinative creativity of common crowd can be stimulated with the aid of SM platforms and newly emerging nonhierarchical organizations. The increasingly networked global economy is forcing companies and nations to think beyond the concepts of traditional supply chains, and view their environment as rapidly evolving business ecosystems in which suppliers and customers are embedded into a network to co-create product values. At the end of the traditional value chain is a customer whose needs are fulfilled through mass-customization. In an SM value chain, by contrast, a customer is not only a “product or service taker” at the end of the chain, but also be significantly involved in the preceding phases, such as R&D, design, component manufacturing, logistics, sales and marketing, after-sales services and product recycling. And the customer needs are sought and fulfilled through the co-created and distributed value networks. In the SM paradigm, the importance and utilization of design, social connectedness, and latent resources are accentuated with the help of the latest supporting technologies. Successful businesses built upon such paradigm have already appeared in the fields like finance, healthcare, and transportation: new bank (ING Direct) was born without physical branch offices; the world’s greatest hotel chain (AirBnB) does not own a single room, and a taxi company (like Uber or Didi) does not have its own cars or drivers. How could this new paradigm be employed elsewhere? Currently, over 70% of shoes do not fully fit feet of customers, many clothing do not fully fit a customer’s body and other requirements. Hence, SM becomes useful for apparel and fashion industry. SM is not simply a technological revolution, but also a social and economic transformation of changing our organizing way to produce what we need in human societies.

An SM mode can help the sustainable, healthy and green development of human societies [18]. SM satisfies a customer’s individual needs and effectively meets the customer’s material needs. So it can save material and energy, and reduce the environmental pollution accordingly. With the support of SM platforms including a social network, cloud platform, and smart mobile terminals, all SM stakeholders like consumers, designers, players, makers, suppliers, brokers, and different service providers, can join win-win collaboration by simply clicking those different function buttons.

Production automation relieves people’s physical labor work using their hands, and knowledge automation partially relieves people’s innovative work using their brains. With the continuous accumulation of manufacturing related knowledge, experience, and wisdom of all the human beings in an SM’s cyber space, most manufacturing participants will become game players in some part of their working time. Nearly any kind of products or services can be produced by a prosumer

from the SM’s cyber space on demand.

SM is an important trend of manufacturing [19]–[20], which is proven by other similar manufacturing modes, like sustainable production [21], cloud manufacturing [22]–[25], mass personalization [26], and customization.

A. SM VS MC

SM brings social networks into the manufacturing field. More and more people can complete SM’s activities together online, like product design, communication and data exchange, and product evaluation.

Through network technology, crowd sourcing and 3D printing, dynamically networked crowd can participate in various product lifecycle processes, e.g., personalized product design, modeling, and manufacturing. In the SM mode, search engine is the core across all the manufacturing processes. Traditional manufacturing is transformed into intelligent manufacturing that can actively collect and respond to a customer’s demand for a personalized product or service.

Comparison results between MC and SM are summarized in Table I. The traditional manufacturing industry mainly considers scale in order to reduce the product cost rather than the customers’ individual demands. MC can meet simple individual demands like the colors and sizes. However, SM is making every effort to overcome the weaknesses of traditional manufacturing by fully realizing the long tail value [27]–[28] as shown in Fig. 3. More specifically, by using MC, one common product can only be divided into the sub-group products whose count is denoted as parameter N according to different requirements of different customers’ groups whose count is defined as parameter M , where MC becomes more expensive if N and M are smaller numbers. MC becomes impossible when N and M exceed their minimum limitation. SM aims to fulfill every customer’s personalized needs through fully personalized (or tailored) products or service, where previous $N : M$ becomes 1:1. By using additive manufacturing, the manufacturing cost of personalized products can be reduced, to meet nearly all needs of product users, and can thus improve the manufacturing competitiveness greatly.

Fig. 3. SM vs traditional manufacturing.

In MC, a customer can choose the product parts and configuration, but not a product design. The product is designed by the product designers normally hired by manufacturers, not by customers or social designers. An SM platform can be updated from MC, where a product can be designed by

customers or according to their instruction across the Internet. In SM, customer can self design his/her product or buy product designs, find and choose product makers or service providers. Social designers can show and sell the product designs and services to customers and makers.

TABLE I
COMPARISON BETWEEN SM AND MC

Content	Mass customization	Social manufacturing
Customer need	Mainly fulfills predefined material need	Fulfills personalized and spiritual needs concurrently
Approach to meet customers' need	Common customized requirements are met by selecting different combinations of product parts	Individual requirements are met by the personalized product design, make and service
Customization mode	Product parts' menus for $N : M$ customization	Personalized product for 1 to 1 customization
Production mode	Modular based mass production; Flexibility is high	Personalized product design and make; Flexibility is higher
Customer's participation	Product part's menu based selection of color, size, and accessories	Interactive personalized product design and make; Customization with any contents and higher accuracy
Supporting technologies	Electrics & Information Technology; Automatic production lines; Manufacturing management system (MES/ ERP/E-business)	Internet of Things; Social Networks; 3D Scanning & Printing; Cloud computing; Knowledge based Intelligent Systems (Cloud based CAD/CAM, MES/ERP, and SM platform)
Advantage	Lowest production cost	Highest value-added and reasonable cost

3D technologies, like 3D scanner, 3D CAD/CAM software, 3D display, and virtual reality, support the interactive 3D design of a personalized product. Additive manufacturing can support enormous and various manufacturing tasks. Additive manufacturing includes 3D printing and rapid prototyping technology.

B. From Social Computing to Social Manufacturing

As social computing [29] lets everyone obtain computing capacity in the society, SM lets everyone obtain innovation and manufacturing capacity. In an SM era, personalized products become popular and profitable, where social customers' needs are seamlessly linked with the SM industry's supply capacity in real-time. Most resources about product innovation, manufacturing and consumption can be found by searching Internet. Internet based search is clearly an important capability. Reductive manufacturing depends on the production scale to reduce the cost. But vast majority of the personalized products belong to Long Tail in Fig. 3, which were classified as handmade luxury items in the past. For personal demand, 3D printing has become an economic solution of SM products, e.g., the

foot last in footwear industry, while most mass production modes become outdated.

3D printing becomes a popular manufacturing mode with its performance improvement and cost decline. Future giant companies are expected to enter the additive manufacturing industry. They will likely grow up into today's Microsoft, Amazon, Google, Facebook, and Alibaba. Google relies on computer server array scale to meet users' information search needs, thus changing the human life and work greatly. In the same way, large-scale SM arrays as illustrated in Fig. 4, consisting of 3D printers and cloud-based production innovation and manufacturing platforms, can meet the personalized product needs conveniently in real-time, and thus change our society profoundly. As shown in Fig. 4, designer, consumer and producer work online, while 3D printers are distributed like the servers in cloud computing. This is why 3D printing will change our manufacturing world; and why SM may bring about another industrial revolution.

Fig. 4. Social manufacturing array with 3D printing centers.

Clearly, the biggest advantage of SM is its capability to transform mind into products directly, and so anyone can participate in the whole process like product design, improvement, publicity, promotion, and marketing through social media and other forms of crowd sourcing package, and can share the product profits according to every partner's contribution. In other words, SM realizes the personalized, real-time, economical production and consumption patterns via 3D printing, network technology, social media, crowd sourcing, etc. to enable everybody on the earth to fully participate in the whole manufacturing lifecycle processes of his/her personalized product.

SM meets some challenges, for example how to "make initial match" between social demands and manufacturing ability in real-time, and how to support the conversion process from product demand to product supply effectively. After the transformation from social computing to SM is realized, the network space and social media can provide the basic conditions and more favorable guarantee for the corresponding integration task of a product's full lifecycles, e.g., product, design, manufacturing and service.

Compared with the cloud manufacturing (CM) [22]–[25], [30], [31], SM is very different. CM does not change the manufacturing mode but puts the traditional manufacturing activities on line by using the cloud technology, while SM

completely changes the manufacturing mode, and from design to manufacturing, all activities can be executed online by crowd sourcing. In short, social computing and 3D printing are the important supporting technologies for SM to become a popular production mode for the future. Only after embedding social computing method in an SM process, the additive manufacturing and SM can possibly lead to a great industrial revolution.

III. BASIC THEORIES AND SUPPORTING TECHNOLOGIES

A. Key Research Themes and Disciplines

The key research topics of SM are shown in Table II [32]–[34]. They include four research themes, five disciplines, and their corresponding research issues. The four research themes are discussed next.

1) *Network structure for SM*: How will the manufacturing globalization trend continue? The future may bring a new wave of manufacturing localization that can take place either in certain clusters or globally. Hence, the suitable SM's network structures, the most promising trends and their interrelations with the chosen theme areas, should be researched through multidisciplinary investigations, and then further operational business planning can be performed.

2) *SM agility*: Manufacturing networks, in their desired state, need to be so agile that no matter what the future global trend driving the location and network structure decisions will be, SM adapts to the emerging trends and requirements. SM networks provide a new networking paradigm under which they co-evolve with the environment, and then a loss of fit can be prevented from occurring. Transdisciplinary investigation and a unique set of methodological tools should increase the understanding of factors affecting and driving the agility of SM networks.

3) *Consumer-driven value creation and value capture dynamics*: The traditional fixed production paradigm is production-driven. In contrast, SM networks are inherently consumer-driven and consequently their whole structure, organization, and processes, i.e., R&D, production, and marketing, are derived backwards from the customer needs and related business opportunities. SM networks are proactive, and always ready to satisfy the emerging needs. Thus, consumer-driven value creation and capture dynamics should be understood, by utilizing a set of purpose-specific tools and methods built with knowledge from multi-disciplines.

4) *Individuals, societies, cultures, and nations in SM networks*: Traditionally, the focus on network paradigms and related industrial designs has mainly been on processes and their corresponding equipment, thus paying no attention to the role of individuals and related collective entities. In the future, however, the individualistic factor will likely play an increasingly critical role. Therefore, the role of human factors in SM networks should be unraveled, based mostly on psychology and cognitive sciences. In order to achieve and maintain the proactive mode, solution providers need relevant individual and collective human behavior knowledge that has some early strategic value. These future knowledge demands and needs for data sharing business model innovations should be analyzed.

B. Basic Theories

1) *Modeling and analysis of SM system*: Main system functions include SM's big data acquisition and social computing analysis; SM's human behavior modeling and analysis; SM's enterprise behavior modeling and analysis; complex dynamic modeling technology and system analysis of all SM's components; infrastructure design and analysis including all SM's components; SM's industry chain, value chain and business mode design and analysis; SM's intelligent manufacturing systems, smart enterprise design and analysis; SM's control and management; and SM's knowledge management and strategy management.

2) *SM system development and pilot verification*: Main research topics include the upon four points.

a) Social design of complex personalized products in a network environment, including 3D scanning and modeling; human-machine interaction for personalized product testing by using 3D virtual reality; and social design platform for complex personalized products in a network environment.

b) SM of complex personalized products in a network environment, including a product's customization for everyone via 3D printing; and intelligent manufacturing technologies like IoT, 3D modeling, Product Lifecycle Management (PLM), and dynamic partnership.

c) Social service of complex personalized products in a network environment, including E-business; demand supply chain; and personalized service.

d) Pilot verification of SM, including an integrated platform for social product design, manufacturing and service. For example, personalized wearable products can be selected as a pilot project to verify the actual application value of the R&D results.

C. Supporting Technologies

SM includes some key technologies like collaborative technology, service oriented architecture (SOA), workflow technology, model driven architecture (MDA) technology, collaborative management systems, enterprise modeling methods, and additive manufacturing, which together make everyone in the whole society possess manufacturing capacity. Network-based collaborative manufacturing service and 3D printing technologies are the important symbols of SM. The SM's main research challenge is how to effectively make use of dynamic netizen group (DNG) [35]–[37], which can be defined as the person groups who dynamically access the same Internet for the similar interests or purposes. Through DNG's crowd sourcing and distributed cooperative forms, the combination of network-based collaborative manufacturing services and 3D printing technology can be realized. Several supporting technologies are discussed.

1) *DNG detection*: With data collection, storage, fusion and analysis, we can detect DNG's hot trend, its dissemination and evaluation; DNG's population types, distribution, organizational structure and social network relationship; the interactive

TABLE II
FOUR RESEARCH THEMES, FIVE DISCIPLINES, AND THEIR RESEARCH ISSUES

Content	Theme 1. network structure of SM	Theme 2. Agility of SM networks	Theme 3. Customer-driven value creation and capture dynamics	Theme 4. Individuals, societies, and nations in SM networks
Discipline I. Manufacturing & Logistics	-What are the global trends affecting SM location decisions in the future?- How these global trends impact the structure of SM networks in the future?	- What are the company-level antecedents of SM network agility in the future?- How should SM and logistics be arranged to proactively satisfy emergent demands?	-How can logistics be used to facilitate customer knowledge acquisition?-How customer knowledge is transferred and integrated into the production and R&D processes?	-How can human intentions be gleaned proactively and relayed to the production?-How human factors of production and logistics affect SM network agility?
Discipline II. Marketing	-What kind of generic structures enable dynamic composition of SM networks? -How do trust and confidence among network parties affect the network structure and composition?	-How to migrate from reactive to proactive agility? -What is the dynamics of need-pulled consumer ecosystems?	-How does opportunity space drive SM network dynamics? - How to implement an effective interface between consumer ecosystems and provider ecosystems?	-How do trust and confidence among the individuals within the value network affect network agility and performance? -How could individuals let their intentions be opened for external access?
Discipline III. Strategic management	-How can resource-based network and social network be combined to better understand, explain, and predict the structure and composition of SM networks? -What factors can explain primary location choices and network structure and composition among SM companies?	-How do entrepreneurial value networks behave under change events incurred by external disturbance? -How does the relatedness of resources among local companies, their partner networks, and customers enable efficient exploration and exploitation activities?	-What structural and composition factors of SM networks facilitate customer knowledge acquisition, assimilation, and exploitation? -How do the value creation dynamics of the established networks differ from the entrepreneurial networks?	-How do the cognition and attitude of its employee, like CEO affect the performance and innovativeness of one company? -How do the interrelations among top management team compositions affect network and company level outcomes?
Discipline IV. Entrepreneurship	-Does spinoff activity and CVC (Corporate venture capital) enable the corporate parent to develop and maintain a viable manufacturing network? -Do internal corporate venturing initiatives help the company partner with others across geographies?	- What kinds of institutional logics may hinder flexibility and agility in a company network? -Does the concept of institutional entrepreneurship promote flexibility in company networks?	-Is the effectual or causal approach to resources and opportunities better in creating customer value? -Is entrepreneurial bricolage more about satisfying the customer's need of the entrepreneurship?	-How central is entrepreneurial resourcefulness in the emergence of SM networks? -How important are the individual's psychological traits, like locus of control, and uncertainty tolerance?
Discipline V. Psychology	-Formal and informal structure of SM networks. -Organization-wide awareness of SM network structures and dynamics. -Decision making in innovation change, action advancement and performance improvement.	-Organization, psychological grounding and implementation of 'agility' -Management of agile actions and behaviors. -Perception of agile operation opportunities. -Required value creating competences. -Agile behavior risk and stake analysis	-Consumer ecosystem sensitivity, awareness and understanding. -Management models for promoting value-creating behaviors. -Performance measures and reward strategies.	-What are behavior drivers in SM networks? -What is the experience of an excellent solution? -Organizational beliefs, practices and support for building individual bonding and commitment to SM networks. -Sensitive and innovative/ renewal atmosphere of SM networks

This table is the modified version from SoMa 2020 project documents [32]–[34].

behavior and product consumption trait of individual Internet user.

2) *SM's modeling for system construction*: For SM's system construction and verification, we should research the evolution modeling of DNG's online/offline behavior and SM's hot trends, the crowd sourcing modeling and simulation of SM's ecosystem. To provide the decision-making basis for SM's control and management, we need to reveal the relationship between SM's complex network structure characteristics

and social media communication mechanisms.

3) *SM's system analysis and evaluation*: The analysis and evaluation of DNG's management mechanisms and strategies help explore the hot spot formation mechanism and development trend in the network society. The analysis and performance evaluation of SM's distributive cooperation mechanisms and logistics processes help explore its dynamic response and corresponding control and management method.

4) *Collaborative modeling of DNG and 3D printing*: With more ICT technologies and social factors being introduced, the existing business modeling framework has deficiencies for modeling SM's new factors. For example, the SM network is more complex than the most of existing frameworks, which refers to social networks, IoT, 3D printing and so on. In order to overcome such deficiencies, we have to develop collaborative models and modeling systems for DNG's collaboration and 3D printing collaboration.

5) *Collaborative mechanism of DNG and 3D printing*: Based on the collaborative mechanism and model of crowd sourcing, a workflow engine and service oriented SM framework can support the collaboration among DNGs by providing such functions as the collaboration of crowd sourcing processes, the service calls and their combination, the distributed and cooperative 3D printers, and human-computer interaction. Then, DNG can help for product innovation, design, manufacturing, and service.

D. Social Manufacturing Platform

An SM platform integrates business processes including product demand, design, R&D, make, to provide services to consumers, designers, makers and shop operators. It is composed of the following five subsystems:

1) *Big data analysis subsystem*: There is a free, orderly, increasingly fierce "collision" among all kinds of social resources, thereby producing the big data with dynamics, diversity, actual and virtual interactions, complexity, uncertainty, and explosive growth. In order to make effective use of big data, the theory and technology like machine learning, data mining, pattern recognition, and artificial intelligence, should be researched to find intelligent information processing mechanisms suitable for SM big data.

2) *Business intelligence subsystem based on cyber-enabled movement organizations (CMO)*: In order to meet the personalized needs of billions of customers, previous "passive response to a customer's product needs" should be changed into "active search for a customer's product needs" in an SM mode. We have to monitor the business focus area, i.e., the interest points of DNG should be monitored constantly and identified quickly and accurately. This requires a business intelligence subsystem based on CMO which consists of massive data and high speed circulation analysis, CMO modeling component, its artificial system, and computational experiments.

3) *Personalized recommendation subsystem*: The subsystem is an advanced business intelligence platform built upon the big data analysis subsystem, to provide the individualized decision support and information service for SM platform users. Its personalized promotion function can provide the innovation or product recommendations according to the user's behavioral characteristics, and realize the personalized advertisement display function dynamically for an intelligent advertisement marketing system. The user behavior data collected by the subsystem, as well as the resource data in the SM platform, should be processed for the structured storage into the existing databases and servers. The subsystem provides recommendation rules suitable for user's behavior, customer demand

and commodity attributes. The subsystem recommends users the needed products, innovation and advertisements, according to their current behavior and demand preference changes.

4) *Intelligent advertisement marketing subsystem*: By using the user interest models in the personalized recommendation subsystem (PRS), the subsystem can accurately calculate the user type, interests, and features of suitable advertisements. By integrating all of its online advertisements, we enable the products or innovations of the SM platform to attract more users and promote the purchasing by using more accurate network marketing, like search bidding, real-time auction, SNS marketing, search engine optimization, mobile advertisement, and advertisement display.

IV. TOWARDS SOCIAL MANUFACTURING AND 3D PRINTING

There exist three types of SM modes: Type 1 SM mode is supported by traditional (reductive) manufacturing; Type 2 SM mode is supported by 3D printer (additive manufacturing); and Type 3 SM mode is supported by both the reductive manufacturing and additive manufacturing, where some parts of a product should be made by Type 1 SM mode, and others made by Type 2 SM mode.

A. Type 1 SM Mode

Type 1 SM mode is supported by reductive manufacturing. Traditionally, a customer selects and buys a product that was designed and made by manufacturers. The customer can go to a shopping mall, select and test a product, pay and own it. Alternatively, the customer can login to an E-business platform like eBay or Alibaba etc., select and pay for the product. Then the product is delivered to the customer-supplied address by logistics provider, like DHL or EXPRESS etc.

In Type 1 SM mode, we take shoes as an example. When every shoe designer and maker provides 3D model data with every pair of shoes on his/her SM platform's account, every customer provides 3D model data of his/her feet and save the data into his/her SM platform's account. Then, SM platform can compare 3D model data of the selected shoe and his/her feet automatically; the customer then can easily find his/her fittest shoes. When the customer wants to design and make his/her personalized shoes with the support of SM platform, he/she should measure and save the 3D model data of his/her feet first, then can create a desired shoes design or buy from others, find the shoe maker, pay for the shoe making, and then the product is made and delivered to the given address. The detailed technologies, solution and application case is described in our new paper of "Moving from mass customization to social manufacturing: a footwear industry case study". And, our research and development result about the SM for apparel industry is written as our new paper "Social manufacturing cloud for high-end apparel customization" [13].

As shown in Fig.5, product design and management functions are added to the existing e-business platform, where

Fig. 5. Type 1 SM platform without 3D printing.

every customer can design his/her personalized product interactively by measuring all parameters and deciding many options; and send the product data to a product maker whenever necessary. Since CAD/product data management (PDM) tool, product data and supporting functions exist in the SM platform and terminals, customers can easily join a product design/choice process, and product design cost can be reduced from a product maker's viewpoint.

B. Type 2 SM mode

Type 2 SM mode is supported by 3D printer. 3D scanning and display technology can greatly enhance the “human-machine interaction” quality. A complex and personalized product can be designed online, and a customer's spiritual need can be met; during the product design stage, a product can be tested and its user experience can be achieved virtually and interactively with 3D model display. The user's desires can be simulated and product consumption is then increased. When a product is wanted, customers just open the product data file and press “PRINT” button, and then the product can be printed out.

To support the three types of users including product consumers, designers or creators, and online shop operators, the SM platform team at Institute of Automation, Chinese Academy of Sciences has developed such functions as “3D Mall”, “Innovation Bar”, and “Online Shop Operators”. In addition, the SM platform also contains a 3D model search engine - “Search 3D” as shown in Fig. 6.

1) *3D mall*: 3D Mall provides consumers with various types of services especially for 3D E-business affairs, like 3D model printing. Consumers can purchase the products existing in the 3D mall; or print out the product by using their own 3D model file. Consumers can also provide their product specification and specify their demands. Then, the operator of the SM platform reviews and confirms the demand, organizes creators to design 3D product models to meet their demands.

Fig. 6. Type 2 SM platform with 3D printing.

2) *Innovation bar*: Innovation Bar provides a 3D product design and communication online channel, where creators can propose and submit their 3D product innovation, and then the operator decides to improve or not, and to print it into a 3D product or not by using an online voting way. In the business operation process, every valuable creator can earn the corresponding income through selling the innovations existing in any process from its birth to move towards the market. As long as members provide a positive contribution to the creative product, they will obtain the corresponding creativity scores according to their contribution. Real-time measurement of the creativity scores can be executed in such processes as the innovation submission, innovation improvement, product naming, product slogans, voting, and comments. After the innovation or 3D products are sold, all contributing members can earn the corresponding income according to their creativity scores.

3) *Online shop operators*: The module provides a platform to Online Shop Operators, through the third party's audit. Everyone can open his/her own online shop, and provides different services and products about 3D printing.

4) *Search 3D*: Search 3D is a search engine specifically for 3D model file search, and such files can support users with

direct online-printing or download for offline-printing. It can obtain 3D product printing capability automatically, without the interaction with a service provider.

C. Type 3 SM mode

Type 3 is supported by both the reductive manufacturing and additive manufacturing, where some parts of a product should be made by Type 1 SM mode, and others made by Type 2 SM mode. So, if the reductive manufacturing plays a dominant role in the whole manufacturing, Type 3 SM mode changes into Type 1 SM mode. If the additive manufacturing plays a dominant role in the whole manufacturing, Type 3 SM mode changes into Type 2 SM mode.

For every industry and enterprise, suitable transformation mode should be selected from Type 1, 2 or 3 SM mode. In the case of footwear industry mainly supported by the reductive manufacturing, suitable transformation mode is Type 1 SM mode. While if the sole and insole parts of shoes are made mainly by 3D printer, then the suitable transformation mode of footwear industry should be Type 3 SM mode.

V. CONCLUSION AND FUTURE WORK

IoT and social networks connect nearly everyone and everything, cloud-based intelligent systems help prosumers design and enjoy any kind of personalized products, and 3D printer can make many products designed online. All of them are important parts to support SM. In SM, the traditional relationships among customer, designer, manufacturer and seller are transformed dramatically through the SM platforms. Customers become prosumers, and prosumers' innovation capacity motivates the whole SM process, instead of only a producer's capacity in traditional manufacturing. Through bidding strategies, product manufacturers can provide on-line product innovation and design platforms for customers and external designers with the existing internal E-business or platforms. Platforms can be integrated into their internal information system and external customer service platform, to provide all necessary functions of a complete demand supply network to external partners. So, SM platform can be built up reasonably for SM business operation.

Definitively, SM is coming with the increasing demands for the personalized products and services. In the future, SM has more and more applications and prospects in the personalized products and services, such as wearable product, consumer electronics, jewelry, medical product, and even education etc. It is of profound theoretical and practical significance to further research the SM's key theories and technologies, and construct and operate SM's key application platforms.

Gang Xiong (M'00-SM'02) received the B. Eng. and the M. Eng. degrees from Department of Precision Instrument, Xi'an University of Science and Technology, Xi'an, China, in 1991 and 1994, respectively, and the Ph.D. degrees in control science and engineering from Shanghai Jiao Tong University, Shanghai, China, in 1996. From 1996 to 1998, he was a Postdoctor and Associate Scientist with the Institute of Industrial Process Control, Zhejiang University. From 1998 to 2001, he was a Senior Research Fellow with the Automation and Control

Institute, Tampere University of Technology, Tampere, Finland. From 2001 to 2007, he was a Specialist and Project Manager with Nokia Corporation, Finland. In 2007, he was a Senior Consultant and Team Leader with Accenture and Chevron, USA. In 2008, he was the Deputy Director of the Informatization Office, Chinese Academy of Science (CAS), Beijing, China. In 2009, he started his present position as a Research Scientist with the State Key Laboratory of Management and Control for Complex Systems, Beijing Engineering Research Center for Intelligent Systems and Technology, Institute of Automation, CAS. In 2011, he became Deputy Director of Beijing Engineering Research Center for Intelligent Systems and Technology, and Deputy Director of Cloud Computing Center, Chinese Academy of Sciences. He is IEEE senior member (2012), INFORMS member, INCOSE member, member of Chinese Association of Automation, General Chair of IEEE SOLI 2011, 2012 and 2013. He has successfully finished more than 40 academic or technical projects funded by Chinese NSFC/MOST/MIT, Finnish TEKES, Academy of Finland, CAS, SINOPEC, Guangdong S&T etc. He is the author or co-author of about 300 refereed journal and conference proceeding papers, including 20 SCI papers, and 180 EI papers. He is editor or co-editor of 2 academic books, the author of 10 chapters. He is author or co-author of about 40 Chinese Patents or PCT, 50 Chinese Software Copyrights. He received 5 awards from IEEE or Government. His research interests include parallel control and management, modeling and optimization of complex systems, cloud computing and big data, intelligent manufacturing, and intelligent transportation systems.

Fei-Yue Wang (S'87-M'89-SM'94-F'03) received the Ph.D. in computer and systems engineering from Rensselaer Polytechnic Institute, Troy, New York in 1990. He joined the University of Arizona in 1990 and became a Professor and Director of the Robotics and Automation Lab (RAL) and Program in Advanced Research for Complex Systems (PARCS). In 1999, he founded the Intelligent Control and Systems Engineering Center at the Institute of Automation, Chinese Academy of Sciences (CAS), Beijing, China, under the support of the Outstanding Oversea Chinese Talents Program from the State Planning Council and "100 Talent Program" from CAS, and in 2002, was appointed as the Director of the Key Lab of Complex Systems and Intelligence Science, CAS. In 2011, he became the State Specially Appointed Expert and the Director of the State Key Laboratory of Management and Control for Complex Systems. Dr. Wang's current research focuses on methods and applications for parallel systems, social computing, and knowledge automation. He was the Founding Editor-in-Chief of the *International Journal of Intelligent Control and Systems* from 1995 to 2000, and the EiC of *IEEE Intelligent Systems* from 2009 to 2012. Currently, he is the EiC of *IEEE Transactions on ITS*. Since 1997, he has served as General or Program Chair of more than 20 IEEE, INFORMS, ACM, ASME conferences. He was the President of IEEE ITS Society from 2005 to 2007, Chinese Association for Science and Technology (CAST, USA) in 2005, and the American Zhu Kezhen Education Foundation from 2007–2008. Since 2008, he is the Vice President and Secretary General of Chinese Association of Automation. Dr. Wang is elected Fellow of IEEE, INCOSE, IFAC, ASME, and AAAS. In 2007, he received the 2nd Class National Prize in Natural Sciences of China and was awarded the Outstanding Scientist by ACM for his work in intelligent control and social computing. He received IEEE ITS Outstanding Application and Research Awards in 2009 and 2011, respectively. In 2014, Dr. Wang received the IEEE SMC Society Norbert Wiener Award.

Timo R. Nyberg received his M.Sc. (Tech) degree in Mechanical Engineering from Helsinki University of Technology, Espoo, Finland, in 1988, and his Dr. (Tech) degree in Automation from Helsinki University of Technology, Espoo, Finland, in 1993. From 1996 to 2002, he was Professor of Automation and Director of Graduate School, Tampere University of Technology, Finland. From 2001 to 2002, he was Senior Vice President, Novo Astra Oy, Finland. From 2002 to 2005, he was Laboratory Director and Management Board member, Helsinki University of Applied Sciences, Finland. Since 2010, he has worked as a Senior Research Fellow and Research Director of School of Science at Aalto University, Finland. Since 2012, he has also been a Visiting Professor of Cloud Computing Center, CAS, China. His research covers enterprise automation systems, business strategies in software, Intelligent Wearable Device and Social Manufacturing. He has finished more than 30 research projects funded by Finnish TEKES, Academy of Finland, EU, and Finnish companies. He is the author or co-author of about 100 refereed journal and conference proceeding papers, and 35 EU/American/Finnish patents. He has experience from both the academic world and industries (Metso, Logica, and Nokia). He has over 15 years of experience of R&D cooperation with Chinese and American companies and universities (Tsinghua Univ., Tongji Univ., MIT, and Stanford Univ.). He has been the board member of Finland & China Trade association.

Xiuqin Shang received her B.Eng. degree in Automation from China University of Petroleum, Qingdao, China, in 2005, and her Ph.D. degree in Control Theory and Control Engineering from Zhejiang University, Hangzhou, China, in 2010. Since 2011, she has been an Assistant Research Scientist in the State Key Laboratory of Management and Control for Complex Systems, Institute of Automation, CAS, China. Her research interests include social manufacturing, industrial process control, data-driven modeling, and parallel management and control.

Mengchu Zhou (S'88-M'90-SM'93-F'03) received his B.S. degree in Control Engineering from Nanjing University of Science and Technology, Nanjing, China in 1983, M.S. degree in Automatic Control from Beijing Institute of Technology, Beijing, China in 1986, and Ph. D. degree in Computer and Systems Engineering from Rensselaer Polytechnic Institute, Troy, NY in 1990. He joined New Jersey Institute of Technology (NJIT), Newark, NJ in 1990, and is now a Distinguished Professor of Electrical and Computer Engineering. His research interests are

in Petri nets, Internet of Things, big data, web services, manufacturing, transportation, and energy systems. He has over 640 publications including 12 books, 330+ journal papers (240+ in IEEE Transactions), and 28 book-chapters. He is the founding Editor of IEEE Press Book Series on Systems Science and Engineering. He is a recipient of Humboldt Research Award for US Senior Scientists, Franklin V. Taylor Memorial Award and the Norbert Wiener Award from IEEE Systems, Man and Cybernetics Society. He is a life member of Chinese Association for Science and Technology-USA and served as its President in 1999. He is a Fellow of International Federation of Automatic Control (IFAC) and American Association for the Advancement of Science (AAAS).

Shuangshuang Li received the B.Eng. degree in Automation from Hangzhou Dianzi University, Hangzhou, China, the M.Eng. degree in Control Theory and Control Engineering from Zhejiang University, Hangzhou, and the Ph.D. degree in Technology of Computer Applications with the State Key Laboratory of Management and Control for Complex Systems, CAS, Beijing, China, in 2007, 2010 and 2013, respectively. Since 2014, he has worked as an Assistant Research Scientist with the State Key Laboratory of Management and Control for Complex Systems, and Qingdao Academy of Intelligent Industries, CAS, China. His research interests include recommendation of multi-agents control systems, high-performance computing, traffic flow prediction, 3D printing, social manufacturing and data mining

Zhen Shen received his B.Eng., M. Eng. and Ph.D. degrees in Control Theory and Control Engineering from Tsinghua University, Beijing, China, from 2000 to 2009. From Oct. 2007 to April 2008, he worked as Visiting Scholar in Boston University, USA. Since 2009, he has worked as an Assistant Research Scientist, and then Associate Research Scientist with the State Key Laboratory of Management and Control for Complex Systems, and the Beijing Engineering Research Center of Intelligent Systems and Technology (2011-), CAS, China.

Chao Guo received the B.E. degree in Automation from the South China University of Technology (SCUT), Guangzhou, China, in 2014. And since 2014, he has been a graduate student in the State Key Laboratory of Management and Control for Complex Systems, and the Cloud Computing Center, Chinese Academy of Science (CAS), China.
