We consider the density response of a spin-imbalanced ultracold Fermi gas in an optical lattice in the Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state. We calculate the collective mode spectrum of the system in the generalized random-phase approximation and find that, although the collective modes are damped even at zero temperature, the damping is weak enough to have well-defined collective modes. We calculate the speed of sound in the gas and show that it is anisotropic due to the anisotropy of the FFLO pairing, which implies an experimental signature for the FFLO state.

I. INTRODUCTION

Ultracold Fermi gases are dilute systems of fermionic atoms cooled down to temperatures where quantum statistics dominate the physics. The unprecedented experimental possibilities of controlling and tuning the ultracold Fermi gas systems have made them an extremely successful tool for simulating a broad range of condensed-matter phenomena [1–3]. To highlight the topic area of this paper, the ability to control the number of each atom species forming the ultracold gas has enabled the experimental study of spin-population imbalanced fermionic superfluidity [4–10].

One candidate for the theoretical description of imbalanced fermionic superfluids is the Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state [11–13], which was originally derived for superconductors in a strong magnetic field. In the FFLO state, the pairing correlations that give rise to superfluidity occur with a finite center-of-mass momentum. This leads to the fact that the FFLO state exhibits a spatially varying order parameter.

In solid-state systems, there has been progress toward finding experimental evidence of the FFLO state in heavy fermion systems [14–17] and also in organic superconductors [18,19]. In the context of ultracold gases in one-dimensional (1D) confinement, there have been experiments [8] in qualitative agreement with theoretical studies on the FFLO state. However, the question about the existence of the FFLO state still remains undecided. This subject has received considerable theoretical attention in the field of ultracold gases, and several experimental procedures to probe the FFLO state have been suggested to complement the direct imaging of the density profile. For instance, the radio frequency (rf) spectroscopy of the FFLO state has been a subject of inquiry [20,21]. In the case of 1D systems, studies have been made on collective mode properties [22], double occupation modulation spectroscopy [23], and Josephson junction analogies [24], as well as rf spectroscopy [25]. Recently, Bragg scattering and rf spectroscopy were proposed for observing the FFLO state in quasi-1D systems [26]. Moreover, noise correlations have been shown to contain information about the FFLO pairing both in 1D and in higher dimensions [27,28].

In this paper, we study the density response and collective modes of the FFLO state. While several collective mode

studies exist on imbalanced Fermi gases, only a few of them consider explicitly the FFLO state [22,29,30]. We concentrate on two-component spin-imbalanced Fermi gases at finite temperature in the lowest band of a two-dimensional (2D) or a quasi-1D optical lattice and with an on-site interaction. The optical lattice is motivated by theoretical studies, indicating that the lattice aids the formation of the FFLO state as the lattice dispersion improves the overlap between the Fermi surfaces of the majority and minority components [31,32]. Our method for calculating the collective mode spectrum is based on the generalized random-phase approximation (GRPA) for the linear response function of the system. The RPA [33] is a standard tool for describing collective modes of interacting fermion systems and it was first applied to the BCS context by Anderson [34]. The method has been used to also describe, e.g., layered superconductors [35] and the BEC-BCS crossover [36,37]. In addition to analyzing the collective mode dispersion and the speed of sound, we also study the damping properties of the collective modes. We find the interesting result that the anisotropic pairing of the FFLO state leads to an anisotropy in the speed of sound in the system. Furthermore, we study a quasi-1D optical lattice in which the tunneling in two directions of a three-dimensional (3D) lattice is restricted, as it has been recently suggested that a quasi-1D geometry would provide optimal conditions for the formation of the FFLO state [38–42].

This paper continues in the next section with an introduction of the Hubbard model and Green's function formalism as well as a rederivation of the FFLO Green's function. Section III A outlines the linear response problem and the Kadanoff-Baym method [43,44] for constructing self-consistent linear response approximations. We derive the linear response function for the FFLO state in Sec. III B. After this, we present our main results in Sec. IV A in which we consider the collective mode spectrum and the speed of sound in two-dimensional square optical lattices. In Sec. IV B, we discuss a quasi-1D geometry. Finally, we conclude our work in Sec. V.

II. THE FFLO STATE IN A LATTICE

A. The theoretical framework

We consider a two-component Fermi gas confined to the lowest energy band of a square (2D) or cubic (3D) lattice with N_L sites, and describe the system with the Hubbard model

*paivi.torma@aalto.fi

with an on-site interaction. The Hamiltonian H_0 of this system is

$$H_0 = - \sum_{\langle \mathbf{r}_1, \mathbf{r}_2 \rangle, \sigma} J_\sigma [\psi_\sigma(\mathbf{r}_1) \psi_\sigma^\dagger(\mathbf{r}_2) + \psi_\sigma(\mathbf{r}_2) \psi_\sigma^\dagger(\mathbf{r}_1)] \\ - \sum_{\mathbf{r}, \sigma} \mu_\sigma \psi_\sigma^\dagger(\mathbf{r}) \psi_\sigma(\mathbf{r}) \\ + \sum_{\mathbf{r}} U_{12} \psi_1^\dagger(\mathbf{r}) \psi_2^\dagger(\mathbf{r}) \psi_2(\mathbf{r}) \psi_1(\mathbf{r}). \quad (1)$$

Here, $\sigma \in \{1, 2\}$ labels the two atomic species, e.g., two hyperfine states of a fermionic atom, and $\psi_\sigma^\dagger$ are the fermionic annihilation and creation operators. [The notation $\psi_\sigma^\dagger(\mathbf{r})$ is slightly more convenient for the Green's function formalism as opposed to the more conventional notation $\hat{c}_{i,\sigma}$.] The position vector of the lattice sites is denoted by $\mathbf{r}$ and the summations run over the set of all lattice sites with $\langle \mathbf{r}_1, \mathbf{r}_2 \rangle$ meaning summation over nearest-neighboring sites. Moreover, J is the nearest-neighbor hopping energy, μ_σ is the chemical potential, and U_{12} is the interaction strength between the two species. A detailed exposition of the connection of the Hubbard model parameters with experimental parameters for ultracold gases can be found, e.g., in [45]. We employ a periodic boundary condition and take the convention $\hbar = 1$.

With the assumption that the system is excited by an external perturbation H_ϕ of the form

$$H_\phi = \sum_{\sigma, \nu, \mathbf{r}_1, \mathbf{r}_2} \phi_{\sigma\nu}(\mathbf{r}_1, \mathbf{r}_2, t) \psi_\sigma^\dagger(\mathbf{r}_1) \psi_\nu(\mathbf{r}_2), \quad (2)$$

the total Hamiltonian is $H = H_0 + H_\phi$. The unperturbed Hamiltonian H_0 is assumed time independent, but the perturbation H_ϕ may have an explicit time dependence.

In the following theoretical treatment, we rely on Green's function techniques in the Matsubara formalism [46,47], i.e., taking time as a complex parameter, which allows us to deal with the finite temperature more efficiently. The thermodynamic average of the operator $\hat{O}$ in interaction picture in the Matsubara formalism is defined as

$$\langle \hat{O} \rangle = \frac{\text{Tr}\{e^{-\beta H_0} T_\tau [S(0, \beta) \hat{O}]\}}{\text{Tr}[e^{-\beta H_0} S(0, \beta)]}. \quad (3)$$

Here, $\beta = \frac{1}{k_B T}$, with k_B the Boltzmann constant and T the temperature. T_τ is the time ordering operator. The complex-time S matrix is defined as

$$S(\tau, \tau') = T_\tau \exp\left(-\int_{\tau'}^{\tau} d\tau'' H_\phi(\tau'')\right). \quad (4)$$

The single-particle Green's function is then defined as

$$G(1, 1') = -\langle T[\psi(1) \psi^\dagger(1')] \rangle. \quad (5)$$

The shorthand notation 1 is used for the variables $\mathbf{r}_1 \tau_1 \sigma_1$.

It is convenient to extend the range of the spin index $\sigma \in \{1, 2\}$ by defining that, for $\sigma \in \{3, 4\}$, one takes $\psi_\sigma = \psi_{\sigma-2}^\dagger$ and $\psi_\sigma^\dagger = \psi_{\sigma-2}$. With this extension, the definition for the Green's function above covers also the so-called anomalous correlators in which two creation or two annihilation operators appear. These functions are essential in describing pairing correlations in the system on the mean-field level. A similar extension is useful for J , μ , ϕ , and U ; for $\sigma_1, \sigma_2 \in \{3, 4\}$, one

defines $J_{\sigma_1} = -J_{\sigma_1-2}$, $\mu_{\sigma_1} = -\mu_{\sigma_1-2}$, $\phi_{\sigma_1, \sigma_2} = -\phi_{\sigma_2-2, \sigma_1-2}$, and $U_{\sigma_1, \sigma_2} = U_{\sigma_1-2, \sigma_2-2}$. In these definitions, the choice of sign allows us to write the equations of motion in the most fluent form.

In certain expressions involving two or more field operators evaluated at the same time τ , the notations τ^+ and τ^- specify the time ordering. These notations imply taking the limits where $\tau^+ \rightarrow \tau$ from the positive imaginary axis and $\tau^- \rightarrow \tau$ from the negative imaginary axis.

The single-particle Green's function follows the equation of motion

$$\int G_0^{-1}(1, \bar{1}) G(\bar{1}, 1') \\ = \delta(1, 1') + \int \phi(1, \bar{1}) G(\bar{1}, 1') + \int \Sigma(1, \bar{1}) G(\bar{1}, 1'). \quad (6)$$

Here, the integral sign is a shorthand notation for summation over position and spin in addition to integration over time. The overbar indicates a variable of summation and integration. Here, the potential ϕ appears formally as nonlocal in time, but only local potentials are required in the work at hand. The inverse noninteracting single-particle Green's function is

$$G_0^{-1}(1, 1') = \left(-\frac{\partial}{\partial \tau} + K_\sigma + \mu(1)\right) \delta(1, 1'), \quad (7)$$

where K_σ is the kinetic energy operator defined by $K_\sigma f(\mathbf{r}) = J_\sigma \sum_{\langle \mathbf{r}, \mathbf{r}' \rangle} [f(\mathbf{r}') - f(\mathbf{r})]$. Furthermore, $\delta(1, 1')$ stands for the Dirac and Kronecker delta for continuous and discrete variables, respectively. For a general two-body interaction, the self-energy Σ is defined as

$$\Sigma(1, 1') = - \int V(1, \bar{1}) G_2(1, \bar{1}^-, \bar{2}, \bar{1}^+) G^{-1}(\bar{2}, 1'), \quad (8)$$

in which the two-particle Green's function G_2 is given by

$$G_2(1, 2, 3, 4) = \langle T_\tau [\psi(1) \psi(2) \psi^\dagger(4) \psi^\dagger(3)] \rangle. \quad (9)$$

For the on-site interaction $V(1, 2) = U_{\sigma_1 \sigma_2} \delta(\mathbf{r}_1, \mathbf{r}_2) \delta(\tau_1 - \tau_2)$, the self-energy simplifies somewhat due to two trivial summations. The equation of motion can also be inverted for G^{-1} as

$$G^{-1}(1, 1') = G_0^{-1}(1, 1') - \phi(1, 1') - \Sigma(1, 1'). \quad (10)$$

B. Imbalanced superfluid in a mean-field model

In this section, we consider the FFLO mean-field description for a spin-imbalanced fermionic superfluid first studied by [11,12]. Notice that, in this section, the focus is on ground-state properties and the external field H_ϕ is not needed.

The equation of motion for the single-particle Green's function involves the two-particle Green's function (9). This object follows again its own equation of motion, which involves the three-particle Green's function and, continuing this way, one derives an infinite set of equations known as the Martin-Schwinger hierarchy. In practice, one needs to decouple this hierarchy on some level in order to find the single-particle Green's function. We resort to a mean-field approximation in Eq. (6). This is often referred to as the

Hartree-Fock-Gor'kov approximation. In this approximation and with the notation $U = U_{12}$, the self-energy is

$$\Sigma = \delta(\mathbf{r}_1 \tau_1, \mathbf{r}'_1 \tau'_1) U \begin{bmatrix} -G_{22} & G_{12} & 0 & -G_{14} \\ G_{21} & -G_{11} & -G_{23} & 0 \\ 0 & -G_{32} & -G_{44} & G_{34} \\ -G_{41} & 0 & G_{43} & -G_{33} \end{bmatrix}. \quad (11)$$

All of the Green's functions appearing in Σ have the variables $(\mathbf{r}_1 \tau_1, \mathbf{r}_1 \tau_1^+)$.

In a system with uniform density, the Hartree terms on the diagonal can be absorbed into the chemical potentials. The Fock-exchange terms with G_{12} , G_{21} , G_{34} , and G_{43} are negligible in solving for the ground state for ultracold Fermi gases, as spin flips are energetically highly unfavorable in experimentally relevant magnetic fields. Finally, we introduce the key element of the mean-field FFLO theory. We assume that the pairing correlations have an oscillating structure, so that the self-energy is

$$\Sigma = \delta(\mathbf{r}_1 \tau_1, \mathbf{r}'_1 \tau'_1) \Delta \begin{bmatrix} 0 & 0 & 0 & e^{2i\mathbf{q} \cdot \mathbf{r}_1} \\ 0 & 0 & -e^{2i\mathbf{q} \cdot \mathbf{r}_1} & 0 \\ 0 & -e^{-2i\mathbf{q} \cdot \mathbf{r}_1} & 0 & 0 \\ e^{-2i\mathbf{q} \cdot \mathbf{r}_1} & 0 & 0 & 0 \end{bmatrix}. \quad (12)$$

Here, $\mathbf{q}$ is the FFLO pairing vector. In the special case of $\mathbf{q} = 0$ and $N_1 = N_2$, the system is reduced to the standard BCS description. The case with $\mathbf{q} = 0$ and $N_1 \neq N_2$ is commonly known as the breached pair (BP) state.

The quantity $\Delta e^{-2i\mathbf{q} \cdot \mathbf{r}_1}$ is the order parameter of the FFLO state. In general, Δ is related to the energy gap of pair-breaking excitations. We point out that this choice of the order parameter is not the only possibility, and it has been shown theoretically [12,13] that, for instance, an order parameter of a cosine form would be energetically more favorable. However, the current choice allows for developing the theory analytically much further, thus making the physics more transparent.

To guarantee the consistency of the mean-field solution, we must have

$$G_{32}(1, 1^+) = \frac{1}{U} \Delta e^{-2i\mathbf{q} \cdot \mathbf{r}_1}. \quad (13)$$

This condition is the FFLO gap equation. In the FFLO self-energy, all the nonzero elements are connected by complex conjugation or anticommutation relations of the field operators. Therefore, one indeed has just one independent gap equation.

One can also fix the expected particle numbers for each atom species N_σ , with the number equations

$$N_\sigma = \sum G_{\sigma\sigma}(\bar{\mathbf{r}}\tau, \bar{\mathbf{r}}\tau^+). \quad (14)$$

However, for a uniform density distribution, one may write the number equation directly in terms of the density (or more precisely the filling fraction) $n_\sigma = N_\sigma/N_L$. The number equation is

$$n_\sigma = G_{\sigma\sigma}(\mathbf{r}\tau, \mathbf{r}\tau^+). \quad (15)$$

In order to find out the values of Δ , μ_1 , and μ_2 for any given FFLO state with pairing vector $\mathbf{q}$ and particle numbers N_1 and N_2 , we need to find a solution for the gap and number equations for the state.

In the following, we derive a closed algebraic form for the FFLO Green's function in momentum and frequency space and rewrite the gap and number equations accordingly.

It is possible to solve the Green's function in the present approximation analytically in the Fourier space. Here, in order to find an algebraically closed set of Fourier components, we have to pay particular attention to the broken translation invariance of the FFLO order parameter. However, our system is still translation invariant with respect to time. Thus, we have $G(\tau_1, \tau_2) = G(\tau_1 - \tau_2)$ and we may take the Fourier transformation in time directly with respect to $\tau_1 - \tau_2$.

We define the Fourier transformation of the Green's function as

$$G(\mathbf{p}_1, \mathbf{p}_2, \omega) = \sum_{\mathbf{r}_1, \mathbf{r}_2} \int_0^\beta d(\tau_1 - \tau_2) e^{i\omega(\tau_1 - \tau_2)} \mathcal{F}(\mathbf{p}_1 \cdot \mathbf{r}_1) \times G(\mathbf{r}_1, \mathbf{r}_2, \tau_1 - \tau_2) \mathcal{F}^\dagger(\mathbf{p}_2 \cdot \mathbf{r}_2), \quad (16)$$

where the Fourier transform matrix $\mathcal{F}$ is given by

$$\mathcal{F}(\mathbf{p}_1 \cdot \mathbf{r}_1) = \begin{bmatrix} e^{-i\mathbf{p}_1 \cdot \mathbf{r}_1} & 0 & 0 & 0 \\ 0 & e^{-i\mathbf{p}_1 \cdot \mathbf{r}_1} & 0 & 0 \\ 0 & 0 & e^{i\mathbf{p}_1 \cdot \mathbf{r}_1} & 0 \\ 0 & 0 & 0 & e^{i\mathbf{p}_1 \cdot \mathbf{r}_1} \end{bmatrix}. \quad (17)$$

Here, $\mathbf{p}_1$ and $\mathbf{p}_2$ are momenta and ω is a frequency (or energy, as we have chosen the convention $\hbar = 1$). The sign convention of $\mathcal{F}$ has been chosen so that it agrees with the Fourier transformation of the field operators. Due to the periodic boundary condition in complex time, also the frequency spectrum is discrete covering the fermionic Matsubara frequencies $\omega = \frac{(2n+1)\pi}{\beta}$, where n is an integer.

The inverse Fourier transformation is

$$G(\mathbf{r}_1, \mathbf{r}_2, \tau_1 - \tau_2) = \frac{1}{\beta N_L} \sum_{\mathbf{p}_1, \mathbf{p}_2, \omega} e^{-i\omega(\tau_1 - \tau_2)} \mathcal{F}^\dagger(\mathbf{p}_1 \cdot \mathbf{r}_1) \times G(\mathbf{p}_1, \mathbf{p}_2, \omega) \mathcal{F}(\mathbf{p}_2 \cdot \mathbf{r}_2). \quad (18)$$

Here, the momentum summations run over the discrete momentum spectrum and the frequency summation over the Matsubara frequencies.

We now Fourier transform the equation of motion (6) for G in the FFLO state. For brevity, we deal first with the $\sigma_1, \sigma_2 \in \{1, 4\}$ block, which has the Fourier transform

$$\begin{bmatrix} i\omega - \xi_1(\mathbf{p}_1) & 0 \\ 0 & i\omega + \xi_2(\mathbf{p}_1) \end{bmatrix} G(\mathbf{p}_1, \mathbf{p}_2, \omega) = \delta_{\mathbf{p}_1, \mathbf{p}_2} I + \Delta \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} G(2\mathbf{q} - \mathbf{p}_1, \mathbf{p}_2, \omega). \quad (19)$$

Here, the noninteracting particle energy $\xi_\sigma(\mathbf{p})$ is

$$\xi_\sigma(\mathbf{p}) = \epsilon(\mathbf{p}) - \mu_\sigma, \quad (20)$$

in which $\epsilon(\mathbf{p})$ is the lattice dispersion.

Equation (19) is mixing different Fourier components of the Green's function due to the broken translation invariance of the order parameter. To be more explicit, for G_{11} , we have

$$[i\omega - \xi_1(\mathbf{p}_1)]G_{11}(\mathbf{p}_1, \mathbf{p}_2, \omega) = \delta_{\mathbf{p}_1, \mathbf{p}_2} + \Delta G_{41}(2\mathbf{q} - \mathbf{p}_1, \mathbf{p}_2, \omega). \quad (21)$$

However, the equation is still closed. Relabeling $\mathbf{p}_1$ with $2\mathbf{q} - \mathbf{p}_1$, the equation for $G_{41}(2\mathbf{q} - \mathbf{p}_1, \mathbf{p}_2, \omega)$ is

$$[i\omega + \xi_2(2\mathbf{q} - \mathbf{p}_1)]G_{41}(2\mathbf{q} - \mathbf{p}_1, \mathbf{p}_2, \omega) = \Delta G_{11}(\mathbf{p}_1, \mathbf{p}_2, \omega). \quad (22)$$

From this pair of equations, it is straightforward to solve for G_{11} and G_{41} . In a similar manner, we find the Green's functions G_{14} and G_{44} . The solution is

$$\begin{aligned} & \begin{bmatrix} G_{11}(\mathbf{p}_1, \mathbf{p}_2, \omega) & G_{14}(\mathbf{p}_1, 2\mathbf{q} - \mathbf{p}_2, \omega) \\ G_{41}(2\mathbf{q} - \mathbf{p}_1, \mathbf{p}_2, \omega) & G_{44}(2\mathbf{q} - \mathbf{p}_1, 2\mathbf{q} - \mathbf{p}_2, \omega) \end{bmatrix} \\ &= \frac{\delta_{\mathbf{p}_1, \mathbf{p}_2}}{[i\omega - \xi_1(\mathbf{p}_1)][i\omega + \xi_2(2\mathbf{q} - \mathbf{p}_1)] - \Delta^2} \\ & \times \begin{bmatrix} i\omega + \xi_2(2\mathbf{q} - \mathbf{p}_1) & \Delta \\ \Delta & i\omega - \xi_1(\mathbf{p}_1) \end{bmatrix}. \end{aligned} \quad (23)$$

The solution for the Green's functions in the matrix block $\sigma_1, \sigma_2 \in \{2, 3\}$ is similar and can be written as

$$\begin{aligned} & \begin{bmatrix} G_{22}(2\mathbf{q} - \mathbf{p}_1, 2\mathbf{q} - \mathbf{p}_2, \omega) & G_{23}(2\mathbf{q} - \mathbf{p}_1, \mathbf{p}_2, \omega) \\ G_{32}(\mathbf{p}_1, 2\mathbf{q} - \mathbf{p}_2, \omega) & G_{33}(\mathbf{p}_1, \mathbf{p}_2, \omega) \end{bmatrix} \\ &= \frac{\delta_{\mathbf{p}_1, \mathbf{p}_2}}{[i\omega + \xi_1(\mathbf{p}_1)][i\omega - \xi_2(2\mathbf{q} - \mathbf{p}_1)] - \Delta^2} \\ & \times \begin{bmatrix} i\omega + \xi_1(\mathbf{p}_1) & -\Delta \\ -\Delta & i\omega - \xi_2(2\mathbf{q} - \mathbf{p}_1) \end{bmatrix}. \end{aligned} \quad (24)$$

Notice that all the other Green's functions $G_{\sigma\nu}$ are trivially zero in the adopted approximation.

The solution can be written in a form that is easier to analyze and is similar to the conventional form for the BCS Green's functions. This final step makes the application of finite-temperature Matsubara summation techniques straightforward. One defines the well-known quasiparticle energies $E_{\pm}$ [11] as

$$\begin{aligned} E_{\pm}(\mathbf{p}) &= \pm \frac{\xi_1(\mathbf{p}) - \xi_2(2\mathbf{q} - \mathbf{p})}{2} \\ &+ \sqrt{\left(\frac{\xi_1(\mathbf{p}) + \xi_2(2\mathbf{q} - \mathbf{p})}{2}\right)^2 + \Delta^2}, \end{aligned} \quad (25)$$

and the coherence factors u and v as

$$u(\mathbf{p}) = \sqrt{\frac{E_+(\mathbf{p}) + \xi_2(2\mathbf{q} - \mathbf{p})}{E_+(\mathbf{p}) + E_-(\mathbf{p})}}, \quad (26)$$

$$v(\mathbf{p}) = \sqrt{\frac{E_-(\mathbf{p}) - \xi_2(2\mathbf{q} - \mathbf{p})}{E_+(\mathbf{p}) + E_-(\mathbf{p})}}. \quad (27)$$

With these definitions, the FFLO Green's functions can be written for the block $\sigma_1, \sigma_2 \in \{1, 4\}$ as

$$\begin{aligned} & \begin{bmatrix} G_{11}(\mathbf{p}_1, \mathbf{p}_2, \omega) & G_{14}(\mathbf{p}_1, 2\mathbf{q} - \mathbf{p}_2, \omega) \\ G_{41}(2\mathbf{q} - \mathbf{p}_1, \mathbf{p}_2, \omega) & G_{44}(2\mathbf{q} - \mathbf{p}_1, 2\mathbf{q} - \mathbf{p}_2, \omega) \end{bmatrix} \\ &= \frac{\delta_{\mathbf{p}_1, \mathbf{p}_2}}{i\omega - E_+(\mathbf{p}_1)} \begin{bmatrix} u(\mathbf{p}_1)^2 & u(\mathbf{p}_1)v(\mathbf{p}_1) \\ u(\mathbf{p}_1)v(\mathbf{p}_1) & v(\mathbf{p}_1)^2 \end{bmatrix} \\ &+ \frac{\delta_{\mathbf{p}_1, \mathbf{p}_2}}{i\omega + E_-(\mathbf{p}_1)} \begin{bmatrix} v(\mathbf{p}_1)^2 & -u(\mathbf{p}_1)v(\mathbf{p}_1) \\ -u(\mathbf{p}_1)v(\mathbf{p}_1) & u(\mathbf{p}_1)^2 \end{bmatrix}, \end{aligned} \quad (28)$$

and for the block $\sigma_1, \sigma_2 \in \{2, 3\}$ as

$$\begin{aligned} & \begin{bmatrix} G_{22}(2\mathbf{q} - \mathbf{p}_1, 2\mathbf{q} - \mathbf{p}_2, \omega) & G_{23}(2\mathbf{q} - \mathbf{p}_1, \mathbf{p}_2, \omega) \\ G_{32}(\mathbf{p}_1, 2\mathbf{q} - \mathbf{p}_2, \omega) & G_{33}(\mathbf{p}_1, \mathbf{p}_2, \omega) \end{bmatrix} \\ &= \frac{\delta_{\mathbf{p}_1, \mathbf{p}_2}}{i\omega - E_-(\mathbf{p}_1)} \begin{bmatrix} u(\mathbf{p}_1)^2 & -u(\mathbf{p}_1)v(\mathbf{p}_1) \\ -u(\mathbf{p}_1)v(\mathbf{p}_1) & v(\mathbf{p}_1)^2 \end{bmatrix} \\ &+ \frac{\delta_{\mathbf{p}_1, \mathbf{p}_2}}{i\omega + E_+(\mathbf{p}_1)} \begin{bmatrix} v(\mathbf{p}_1)^2 & u(\mathbf{p}_1)v(\mathbf{p}_1) \\ u(\mathbf{p}_1)v(\mathbf{p}_1) & u(\mathbf{p}_1)^2 \end{bmatrix}. \end{aligned} \quad (29)$$

While the normal Green's functions are diagonal in momentum space, the anomalous Green's functions are not, reflecting the oscillatory structure of the pairing field.

Finally, we present the gap equation (13) and the number equations (14) in Fourier space. The inverse Fourier transform of $G_{32}(1, 1^+)$ appearing in the gap equation is

$$\begin{aligned} G_{32}(\mathbf{r}\tau, \mathbf{r}\tau^+) &= \frac{1}{N_L} \sum_{\mathbf{p}} e^{-2i\mathbf{q}\cdot\mathbf{r}} u(\mathbf{p})v(\mathbf{p}) \\ &\times \{1 - n_F[E_+(\mathbf{p})] - n_F[E_-(\mathbf{p})]\}, \end{aligned} \quad (30)$$

in which the Fermi distribution n_F has been obtained from the Matsubara summation

$$n_F(E) = \frac{1}{\beta} \sum_{\omega} \frac{e^{i\omega(\tau^+ - \tau)}}{i\omega - E}. \quad (31)$$

Thus, the gap equation is

$$\frac{\Delta}{U} = \frac{1}{N_L} \sum_{\mathbf{p}} u(\mathbf{p})v(\mathbf{p})\{1 - n_F[E_+(\mathbf{p})] - n_F[E_-(\mathbf{p})]\}. \quad (32)$$

Similarly, the number equations in terms of the filling fraction are

$$\begin{aligned} n_1 &= G_{11}(\mathbf{r}\tau, \mathbf{r}\tau^+) = \frac{1}{N_L} \sum_{\mathbf{p}} u(\mathbf{p})^2 n_F[E_+(\mathbf{p})] + v(\mathbf{p})^2 \\ &\times \{1 - n_F[E_-(\mathbf{p})]\} \end{aligned} \quad (33)$$

and

$$\begin{aligned} n_2 &= G_{22}(\mathbf{r}\tau, \mathbf{r}\tau^+) = \frac{1}{N_L} \sum_{\mathbf{p}} u(\mathbf{p})^2 n_F[E_-(\mathbf{p})] + v(\mathbf{p})^2 \\ &\times \{1 - n_F[E_+(\mathbf{p})]\}. \end{aligned} \quad (34)$$

III. DENSITY RESPONSE IN THE FFLO STATE

A. Linear response theory

Having established a ground-state description for the imbalanced superfluid, let us turn to study density fluctuations

caused by potentials that couple to the particle density. The Hamiltonian H_ϕ for such external potentials is of the form

$$H_\phi = \int \phi_1(\bar{\mathbf{r}}t) \psi_1^\dagger(\bar{\mathbf{r}}) \psi_1(\bar{\mathbf{r}}) + \int \phi_2(\bar{\mathbf{r}}t) \psi_2^\dagger(\bar{\mathbf{r}}) \psi_2(\bar{\mathbf{r}}). \quad (35)$$

Now, if and when solving the system with $H = H_0 + H_\phi$ directly is not feasible, progress can be made by assuming that H_ϕ is a small perturbation. To find out the effect of H_ϕ for instance on the density of atom species $\sigma = 1$, one can then write $n_{\sigma_1}(\mathbf{r}t)$ as a variational series with respect to ϕ and truncate this series to the first order, obtaining

$$n_1(\mathbf{r}t) = [n_1(\mathbf{r}t)] + \int \phi_1(\bar{\mathbf{r}}t) \left(\frac{\delta n_1(\mathbf{r}t)}{\delta \phi_1(\bar{\mathbf{r}}t)} \right)_{\phi=0} + \int \phi_2(\bar{\mathbf{r}}t) \left(\frac{\delta n_1(\mathbf{r}t)}{\delta \phi_2(\bar{\mathbf{r}}t)} \right)_{\phi=0}. \quad (36)$$

Let us continue in the Matsubara formalism. The concept above can be generalized for any Green's function by writing it as a variational series to the first order with respect to $\phi(1,2)$ so that

$$G(1,1') = [G(1,1')] + \int \phi(\bar{2},\bar{3}) \left(\frac{\delta G(1,1')}{\delta \phi(\bar{2},\bar{3})} \right)_{\phi=0}. \quad (37)$$

Notice again that the overbar indicates summation and integration over position, time, and spin. The variational derivative in the equation above defines the linear response function

$$L(12,1'2') = \left(\frac{\delta G(1,1')}{\delta \phi(2',2)} \right)_{\phi=0}. \quad (38)$$

For example, the density is given by $n_{\sigma_1}(\mathbf{r}_1\tau_1) = G(1,1^+)$ so $L(12,1^+2')$ would give the density response function.

The linear response function carries information about the excited states of the unperturbed system. If one is able to solve the linear response function, one can then extract from it the excitation spectrum of the system. For instance, the collective density modes appear as simple poles of the density response function in frequency space.

Following Kadanoff and Baym [43,44], one can derive an equation for the linear response function from the equation of motion (10). To outline the derivation of their result briefly, let us begin by taking the variational derivative of the identity $\int GG^{-1} = \delta$, which yields

$$\frac{\delta G(1,1')}{\delta \phi(2',2)} = - \int G(1,\bar{3}) \frac{\delta G^{-1}(\bar{3},\bar{4})}{\delta \phi(2',2)} G(\bar{4},1'). \quad (39)$$

Now, inserting G^{-1} from (10) into the previous equation, evaluating the expression at $\phi = 0$, and identifying L we get

$$L(12,1'2') = \int \left[G(1,\bar{3}) \left(\frac{\delta \phi(\bar{3},\bar{4})}{\delta \phi(2',2)} + \frac{\delta \Sigma(\bar{3},\bar{4})}{\delta \phi(2',2)} \right) G(\bar{4},1') \right]. \quad (40)$$

Since the self-energy does not depend explicitly on the external perturbation, the chain rule of differentiation gives

$$\begin{aligned} \frac{\delta \Sigma(3,4)}{\delta \phi(2',2)} &= \int \frac{\delta \Sigma(3,4)}{\delta G(\bar{5},\bar{6})} \frac{\delta G(\bar{5},\bar{6})}{\delta \phi(2',2)} \\ &= \int \frac{\delta \Sigma(3,4)}{\delta G(\bar{5},\bar{6})} L(\bar{5}2,\bar{6}2'). \end{aligned} \quad (41)$$

Therefore, one may write Eq. (40) explicitly as an integral equation for the linear response function

$$\begin{aligned} L(12,1'2') &= \int G(1,\bar{3})_{\phi=0} G(\bar{4},1')_{\phi=0} \left(\frac{\delta \phi(\bar{3},\bar{4})}{\delta \phi(2',2)} \right)_{\phi=0} \\ &+ \int G(1,\bar{3})_{\phi=0} G(\bar{4},1')_{\phi=0} \left(\frac{\delta \Sigma(\bar{3},\bar{4})}{\delta G(\bar{5},\bar{6})} \right)_{\phi=0} L(\bar{5}2,\bar{6}2'), \end{aligned} \quad (42)$$

which is the result of [43,44]. This equation for the response function guarantees a self-consistent theory in the sense that the linear response function obeys the same conservation laws as does the single-particle Green's function. From this point on, we leave out the notation $\phi = 0$ as in the following, all of the variational derivatives are evaluated at $\phi = 0$. Notice that in the equation above there is a trivial variational derivative

$$\frac{\delta \phi(3,4)}{\delta \phi(1,2)} = \delta(\mathbf{r}_3\tau_3 - \mathbf{r}_1\tau_1) \delta(\mathbf{r}_4\tau_4 - \mathbf{r}_2\tau_2) \delta(\sigma_3\sigma_4, \sigma_1\sigma_2), \quad (43)$$

where we have the notation

$$\delta(\sigma_3\sigma_4, \sigma_1\sigma_2) = \delta(\sigma_3, \sigma_1) \delta(\sigma_4, \sigma_2) - \delta(\sigma_4, \sigma_1 \pm 2) \delta(\sigma_3, \sigma_2 \pm 2). \quad (44)$$

The second term in this definition owes to the fact that, for the extended index $\sigma_1, \sigma_2 \in \{3,4\}$, we have $\phi_{\sigma_1, \sigma_2} = -\phi_{\sigma_2-2, \sigma_1-2}$.

B. Derivation of the FFLO density response function

We derive the FFLO density response function in this section. The Kadanoff-Baym method applied to the Hartree-Fock-Gor'kov approximation (11) leads to the generalized random-phase approximation. We now extend this to the case of a FFLO state. In the density response problem, several simplifications to the general equation for the linear response function are apparent. First of all, it is sufficient to consider a local perturbation of the form $\phi(1,2) = \phi_{\sigma_1\sigma_2}(\mathbf{r}_1\tau_1) \delta(\mathbf{r}_1\tau_1 - \mathbf{r}_2\tau_2)$. Furthermore, the density operator itself as well as all the Green's functions in the self-energy are local. Thus, the density response function of which we are interested in contains only terms with $\mathbf{r}_1 = \mathbf{r}'_1$, $\tau_1 = \tau'_1$ and $\mathbf{r}_2 = \mathbf{r}'_2$, $\tau_2 = \tau'_2$. Moreover, due to the time translation invariance, this response function depends only on the time difference $\tau_1 - \tau_2$. We then find it suitable for our purposes to define the notation

$$L_{\sigma_1\sigma_2\sigma'_1\sigma'_2}(\mathbf{r}_1, \mathbf{r}_2, \tau_1 - \tau_2) = \delta(\mathbf{r}_1\tau_1, \mathbf{r}'_1\tau'_1) \delta(\mathbf{r}_2\tau_2, \mathbf{r}'_2\tau'_2) L(12,1'2'). \quad (45)$$

The density response functions $\frac{\delta n_1}{\delta \phi_1}$ and $\frac{\delta n_1}{\delta \phi_2}$ in Eq. (36) correspond to L_{1111} and L_{1212} , respectively.

Equation (40) now reads as

$$\begin{aligned} L_{\sigma_1\sigma_2\sigma'_1\sigma'_2}(\mathbf{r}_1, \mathbf{r}_2, \tau_1 - \tau_2) &= \sum G_{\sigma_1\bar{\sigma}_3}(\mathbf{r}_1, \mathbf{r}_2, \tau_1 - \tau_2) G_{\bar{\sigma}_4\sigma'_1}(\mathbf{r}_2, \mathbf{r}_1, \tau_2 - \tau_1) \\ &\times \delta(\bar{\sigma}_3\bar{\sigma}_4, \sigma'_2\sigma_2) + \int G_{\sigma_1\bar{\sigma}_3}(\mathbf{r}_1, \bar{\mathbf{r}}_3, \tau_1 - \bar{\tau}_3) \\ &\times G_{\bar{\sigma}_4\sigma'_1}(\bar{\mathbf{r}}_3, \mathbf{r}_1, \bar{\tau}_3 - \tau_1) \frac{\delta \Sigma_{\bar{\sigma}_3\bar{\sigma}_4}(\bar{\mathbf{r}}_3, \mathbf{r}_2, \bar{\tau}_3 - \tau_2)}{\delta \phi_{\sigma'_2\sigma_2}}. \end{aligned} \quad (46)$$

Let us now write down explicitly the equation for L_{1111} to show how to proceed with the solution. Since many of the FFLO Green's functions are identically zero, just one term

remains from the direct coupling to the external perturbation, which is the first term in Eq. (46). Similarly, only four nonzero terms arise from the second term in Eq. (46):

$$\begin{aligned}
 L_{1111}(\mathbf{r}_1, \mathbf{r}_2, \tau_1 - \tau_2) &= G_{11}(\mathbf{r}_1, \mathbf{r}_2, \tau_1 - \tau_2) G_{11}(\mathbf{r}_2, \mathbf{r}_1, \tau_2 - \tau_1) \\
 &+ U \int G_{14}(\mathbf{r}_1, \bar{\mathbf{r}}_3, \tau_1 - \bar{\tau}_3) G_{41}(\bar{\mathbf{r}}_3, \mathbf{r}_1, \bar{\tau}_3 - \tau_1) L_{1111}(\bar{\mathbf{r}}_3, \mathbf{r}_2, \bar{\tau}_3 - \tau_2) \\
 &- U \int G_{11}(\mathbf{r}_1, \bar{\mathbf{r}}_3, \tau_1 - \bar{\tau}_3) G_{41}(\bar{\mathbf{r}}_3, \mathbf{r}_1, \bar{\tau}_3 - \tau_1) L_{1141}(\bar{\mathbf{r}}_3, \mathbf{r}_2, \bar{\tau}_3 - \tau_2) \\
 &- U \int G_{14}(\mathbf{r}_1, \bar{\mathbf{r}}_3, \tau_1 - \bar{\tau}_3) G_{11}(\bar{\mathbf{r}}_3, \mathbf{r}_1, \bar{\tau}_3 - \tau_1) L_{4111}(\bar{\mathbf{r}}_3, \mathbf{r}_2, \bar{\tau}_3 - \tau_2) \\
 &+ U \int G_{11}(\mathbf{r}_1, \bar{\mathbf{r}}_3, \tau_1 - \bar{\tau}_3) G_{11}(\bar{\mathbf{r}}_3, \mathbf{r}_1, \bar{\tau}_3 - \tau_1) L_{4141}(\bar{\mathbf{r}}_3, \mathbf{r}_2, \bar{\tau}_3 - \tau_2). \quad (47)
 \end{aligned}$$

In forming this equation, we have used the identities $L_{3131} = -L_{1111}$ and $L_{2121} = -L_{4141}$. This substitution owes to a more general identity: Noting the definitions (38) of the response function and (5) of the Green's function, one concludes based on equal time anticommutation relations that

$$\begin{aligned}
 L_{\sigma, \alpha, \nu, \beta}(\mathbf{r}_1, \mathbf{r}_2, \tau) &= -L_{\sigma+2, \alpha, \nu+2, \beta}(\mathbf{r}_1, \mathbf{r}_2, \tau), \\
 L_{\sigma+2, \alpha, \nu, \beta}(\mathbf{r}_1, \mathbf{r}_2, \tau) &= -L_{\sigma, \alpha, \nu+2, \beta}(\mathbf{r}_1, \mathbf{r}_2, \tau). \quad (48)
 \end{aligned}$$

As with the Green's function, the integral equation for L_{1111} [Eq. (47)] can be cast into an algebraic equation in Fourier space. Notice that, for instance, in spherically symmetric harmonic trapping geometries, one can make similar progress with the choice of the harmonic-oscillator states as basis functions [48]. We use the same Fourier transformation convention for $L_{\sigma, 1, \nu, 1} = \frac{\delta G_{\sigma\nu}}{\delta \phi_{11}}$ as we defined for $G_{\sigma\nu}$ in (16), i.e., the sign convention is given by σ and ν . The Fourier transformation yields for L_{1111} , i.e., $\frac{\delta n_1}{\delta \phi_{11}}$, the equation

$$\begin{aligned}
 L_{1111}(\mathbf{p}_1, \mathbf{p}_2, \omega) &= \delta_{\mathbf{p}_1, \mathbf{p}_2} \Pi_{1111}(\mathbf{p}_1, \omega) \\
 &+ U \Pi_{1441}(\mathbf{p}_1, \omega) L_{1111}(\mathbf{p}_1, \mathbf{p}_2, \omega) \\
 &- U \Pi_{1141}(\mathbf{p}_1, \omega) L_{1141}(2\mathbf{q} + \mathbf{p}_1, -\mathbf{p}_2, \omega) \\
 &- U \Pi_{1411}(\mathbf{p}_1, \omega) L_{4111}(2\mathbf{q} - \mathbf{p}_1, \mathbf{p}_2, \omega) \\
 &+ U \Pi_{1111}(\mathbf{p}_1, \omega) L_{4141}(-\mathbf{p}_1, -\mathbf{p}_2, \omega). \quad (49)
 \end{aligned}$$

Here, we have the notation

$$\begin{aligned}
 \Pi_{\sigma_1 \sigma_2 \sigma_3 \sigma_4}(\mathbf{p}+, \omega) &= \frac{1}{\beta N_L} \sum_{\mathbf{s}, \chi} G_{\sigma_1 \sigma_2}[\lambda_{\sigma_1}(\mathbf{p} + \mathbf{s}), \lambda_{\sigma_2}(\mathbf{p} + \mathbf{s}), \chi + \omega] \\
 &\times G_{\sigma_3 \sigma_4}[\lambda_{\sigma_3}(\mathbf{s}), \lambda_{\sigma_4}(\mathbf{s}), \chi], \quad (50)
 \end{aligned}$$

where $\lambda_\sigma(\mathbf{p})$ is defined so that

$$\begin{aligned}
 \lambda_\sigma(\mathbf{p}) &= \mathbf{p}, \quad \sigma \in \{1, 2\} \\
 \lambda_\sigma(\mathbf{p}) &= 2\mathbf{q} - \mathbf{p}, \quad \sigma \in \{3, 4\}. \quad (51)
 \end{aligned}$$

Equation (47) is rather analogous to the previously solved equation for the FFLO Green's function. We see that we need to construct equations also for L_{1141} , L_{4111} , and L_{4141} . By using again the symmetry property (48) for these equations, we find out that no other linear response functions enter the equation. The final task is to identify those Fourier components that form a closed equation. With this rationale, one arrives at the following matrix equation:

$$M^{(1)}(\mathbf{p}_1) L^{(1)}(\mathbf{p}_1, \mathbf{p}_2) = \delta_{\mathbf{p}_1, \mathbf{p}_2} \Pi^{(1)}(\mathbf{p}_1). \quad (52)$$

Here the vector of linear response functions $L^{(1)}$ is defined as

$$L^{(1)}(\mathbf{p}_1, \mathbf{p}_2) = \begin{bmatrix} L_{1111}(\mathbf{p}_1, \mathbf{p}_2) \\ L_{1141}(2\mathbf{q} + \mathbf{p}_1, -\mathbf{p}_2) \\ L_{4111}(2\mathbf{q} - \mathbf{p}_1, \mathbf{p}_2) \\ L_{4141}(-\mathbf{p}_1, -\mathbf{p}_2) \end{bmatrix}. \quad (53)$$

On the right-hand side, $\Pi^{(1)}$ contains the terms from the direct coupling to the external perturbation

$$\Pi^{(1)}(\mathbf{p}_1) = \begin{bmatrix} \Pi_{1111}(\mathbf{p}_1) \\ \Pi_{1141}(\mathbf{p}_1) \\ \Pi_{4111}(\mathbf{p}_1) \\ \Pi_{4141}(\mathbf{p}_1) \end{bmatrix}. \quad (54)$$

The coefficient matrix $M^{(1)}$ is given by

$$M^{(1)}(\mathbf{p}_1) = I + U \begin{bmatrix} -\Pi_{1441}(\mathbf{p}_1) & \Pi_{1141}(\mathbf{p}_1) & \Pi_{1411}(\mathbf{p}_1) & -\Pi_{1111}(\mathbf{p}_1) \\ -\Pi_{1444}(\mathbf{p}_1) & \Pi_{1144}(\mathbf{p}_1) & \Pi_{1414}(\mathbf{p}_1) & -\Pi_{1114}(\mathbf{p}_1) \\ -\Pi_{4441}(\mathbf{p}_1) & \Pi_{4141}(\mathbf{p}_1) & \Pi_{4411}(\mathbf{p}_1) & -\Pi_{4111}(\mathbf{p}_1) \\ -\Pi_{4444}(\mathbf{p}_1) & \Pi_{4144}(\mathbf{p}_1) & \Pi_{4414}(\mathbf{p}_1) & -\Pi_{4114}(\mathbf{p}_1) \end{bmatrix}. \quad (55)$$

One derives similarly for L_{1212} , i.e., $\frac{\delta n_1}{\delta \phi_2}$, the equation

$$M^{(2)}(\mathbf{p}_1)L^{(2)}(\mathbf{p}_1, \mathbf{p}_2) = -\delta_{\mathbf{p}_1, \mathbf{p}_2}\Pi^{(2)}(\mathbf{p}_1), \quad (56)$$

in which $L^{(2)}$ stands for

$$L^{(2)}(\mathbf{p}_1, \mathbf{p}_2) = \begin{bmatrix} L_{1212}(\mathbf{p}_1, \mathbf{p}_2) \\ L_{1242}(2\mathbf{q} + \mathbf{p}_1, -\mathbf{p}_2) \\ L_{4212}(2\mathbf{q} - \mathbf{p}_1, \mathbf{p}_2) \\ L_{4242}(-\mathbf{p}_1, -\mathbf{p}_2) \end{bmatrix}, \quad (57)$$

and $\Pi^{(2)}$ is

$$\Pi^{(2)}(\mathbf{p}_1) = \begin{bmatrix} \Pi_{1441}(\mathbf{p}_1) \\ \Pi_{1444}(\mathbf{p}_1) \\ \Pi_{4441}(\mathbf{p}_1) \\ \Pi_{4444}(\mathbf{p}_1) \end{bmatrix}. \quad (58)$$

The coefficient matrix $M^{(2)}$ turns out to be the same as $M^{(1)}$.

In our theoretical treatment, we have an obvious symmetry with respect to interchanging indices 1 and 2 and indices 3 and 4. Therefore, we obtain the equation for the density response functions L_{2222} and L_{2121} directly from the results above.

The frequency summation in the definition of Π [Eq. (50)] can be handled analytically. One applies the identity

$$\frac{1}{\beta} \sum_{\chi} \frac{1}{i(\omega + \chi) - E_1} \frac{1}{i\chi - E_2} = \frac{n_F(E_1) - n_F(E_2)}{E_1 - E_2 - i\omega} \quad (59)$$

to the four cross terms that arise when one inserts the Fourier-transformed Green's functions (28) and (29) to Eq. (50). The momentum summation in Eq. (50) needs to be carried out numerically after which one simply inverts the matrix equations presented above to obtain the Matsubara, i.e., imaginary frequency, response function. From this, the real frequency retarded linear response function is obtained by means of analytical continuation.

IV. RESULTS

A. 2D square lattice

In the following results, we consider a system in a two-dimensional square optical lattice with lattice constant d and $N_L = N_x N_y = 40\,000$ lattice sites with $N_x = N_y = 200$ lattice sites in each direction. We assume that the perturbation potential is the same for both atom species, i.e., $\phi_1 = \phi_2$ in which case it is most natural to study the density response function $\chi_1(\mathbf{k}, \omega) = L_{1111}(\mathbf{k}, \omega) + L_{1212}(\mathbf{k}, \omega)$, where L_{1111} and L_{1212} are the responses of density n_1 to potentials ϕ_1 and ϕ_2 , respectively. In the following, the parameters are chosen so that n_1 is the density of the majority component. Similar conclusions hold also for the response of the minority component. The assumption of $\phi_1 = \phi_2$ is not a crucial one as the collective mode dispersion is the same for all choices of these potentials. Moreover, we assume that the FFLO vector $\mathbf{q}$ is directed along the x axis.

We solve Eqs. (52) and (56) numerically for imaginary frequencies. We then use a Padé approximant [49] to carry out the analytical continuation and obtain the response function for complex frequencies.

In Fig. 1, we plot the real part of the density response function for typical parameters as a function of the wave vector

FIG. 1. (Color online) The real part of the density response $\chi_1(\mathbf{k}, \omega)$ for typical parameters $\mu_1 = 3.5J$, $\mu_2 = 2.5J$, $T = 0.07J$, $U = -3.0J$, $\Delta = 0.27J$, and $q = 12\pi/(dN_x)$ with $\mathbf{k}$ parallel to $\mathbf{q}$. The collective mode is seen as a clear divergent behavior of the density response. The lone peak on the k_x axis is a numerical instability.

$\mathbf{k}$ and the real frequency ω . In this figure, we have chosen $\mathbf{k}$ parallel to $\mathbf{q}$. The collective density mode appears as a nearly diverging feature of the density response at a particular wave vector $\mathbf{k}$ and frequency ω . Toward higher wave vectors, we see a typical broadening of this feature owing to the increase of damping. The actual eigenfrequency of the mode is complex with the frequency $\omega - i\gamma$, where γ is the damping rate. For the small damping rates, the response has a very sharp jump also as a function of real frequencies. The collective mode is gapless with a linear dispersion for small $\mathbf{k}$. It corresponds to the Anderson-Bogoliubov phonon of the BCS state of a neutral Fermi gas [34].

We solve the dispersion relation $\omega(\mathbf{k})$ and the damping rate $\gamma(\mathbf{k})$ by solving the poles of the response function χ_1 . We plot $\omega(\mathbf{k})$ and $\gamma(\mathbf{k})$ in Fig. 2 for wave vectors along the x and y axes, i.e., parallel and perpendicular to the FFLO vector $\mathbf{q}$. Notice that the numerical method produces several instabilities in the damping rate at higher wave vectors, while the real frequency ω is far more stable. The speed of sound to the direction of the x axis, c_x , can be obtained from the dispersion by the definition

$$c_x = \left. \frac{d\omega(k\mathbf{e}_x)}{dk} \right|_{k \rightarrow 0}, \quad (60)$$

where $\mathbf{e}_x$ is the unit vector in the x direction. One defines c_y similarly. For the dispersions presented in Fig. 2, we obtain $c_x = 1.39Jd$ and $c_y = 1.24Jd$. We observe that the finite FFLO vector causes a clear difference between the parallel and perpendicular (w.r.t. $\mathbf{q}$) speeds of sound. In this case, the relative difference in the sound propagation is $c_x/c_y - 1 = 12\%$. This observation suggests immediately an experiment in which one creates a local density perturbation in the system and then monitors the propagation of this perturbation to collect information about the FFLO state. Such an experiment would create a rather remarkable contrast with, e.g., a breached pairing state, which is isotropic with $c_x = c_y$.

FIG. 2. (Color online) The dispersion relation $\omega(\mathbf{k})$ and the damping rate $\gamma(\mathbf{k})$ calculated for $\mu_1 = 3.5J$, $\mu_2 = 2.5J$, $T = 0.07J$, $U = 3.0J$, $\Delta = 0.27J$, and $q = 12\pi/(dN_x)$ along the x axis (circles) and y axis (diamonds). The FFLO vector $\mathbf{q}$ is directed along the x axis and this anisotropy creates a clear difference between the two dispersions and damping rates.

Turning back to analyze the damping rates presented in Fig. 2, we find that the damping rate is only a fraction of the mode frequency, with $\gamma_x/\omega_x = 5\%$ and $\gamma_y/\omega_y = 7\%$ for the lowest frequencies. With this observation, we conclude that the collective modes can be considered as well-defined elementary excitations of the FFLO state. An important aspect here is that the damping is fundamentally not an effect caused by the finite temperature. In contrast to the BCS state, the FFLO state contains also at zero temperature unpaired quasiparticles that cause a finite lifetime for the collective modes. In Fig. 3, we illustrate the locations of the quasiparticle channels for the system of Figs. 1 and 2. Indeed, the collective mode dispersion lies deep within the region containing quasiparticle transitions. To compare, the pair-breaking excitations are present also in a BCS state of a neutral Fermi gas, but at zero temperature, the quasiparticle transitions are completely absent and the Anderson-Bogoliubov phonon is thus undamped.

FIG. 3. (Color online) An illustration of the quasiparticle transitions for a system with $\mu_1 = 3.5J$, $\mu_2 = 2.5J$, $\Delta = 0.27J$, and $q = 12\pi/(dN_x)$ along the x axis, corresponding to a zero-temperature Fermi distribution. A cross denotes a transition of a single quasiparticle and a plus denotes a pair breaking, which involves the creation of two quasiparticles. Notice that the figure shows only the positions of the quasiparticle excitations, not their relative weights. The small void regions along the k_x axis owe to the finite system size.

In Fig. 4, we study the speed of sound as a function of the length of the FFLO vector q when the other system parameters are held constant and the gap is solved from the gap equation (13) for each q . In the range $qdN_x/(2\pi) = 4-8$, we find an anisotropy of 5%–7%. The figure also indicates that the speed of sound tends to increase with q . This is caused by the fact that the gap Δ decreases when q increases, which in turn causes the increase in the speed of sound. The two smallest possible FFLO vectors have been left out since they lead to a pair-breaking gap, which is larger than the chemical potential difference $2\Delta > |\mu_1 - \mu_2|$ and, therefore, the state is not physically relevant.

We then turn to examine the effect of the polarization $P = (N_1 - N_2)/(N_1 + N_2)$ on the speed of sound in Fig. 5. Technically, we vary the chemical potential difference while holding the average chemical potential $(\mu_1 + \mu_2)/2$ and other system parameters constant. We find that the anisotropy in the sound propagation increases from 2% to 10% when the polarization increases to the value $P = 0.2$. Also, the speed of sound itself increases with the polarization, and the explanation is analogous to the discussion of the FFLO vector above: while holding the other system parameters fixed, the gap Δ decreases with the chemical potential difference, or the polarization. In the range $P < 0.11$, the pair-breaking gap is larger than the chemical potential difference, and the FFLO ansatz does not produce a physically relevant state.

We examine the temperature dependence of the speed of sound in Fig. 6. First, we stress that while the temperature does affect the dispersion relation, it always remains true that, in the small wavelength limit, the collective mode is massless and the dispersion goes linearly to zero. We see that the speed of sound and, in particular, the anisotropy is fairly robust against changes in temperature deep in the superfluid phase.

FIG. 4. (Color online) The speed of sound parallel (c_x , circles) and perpendicular (c_y , diamonds) to the FFLO vector $\mathbf{q} = q\mathbf{e}_x$ as a function of length of the FFLO vector q for a system with $\mu_1 = 3.4J$, $\mu_2 = 2.6J$, $T = 0.1J$, and $U = -2.8J$. The gap Δ is solved from the gap equation (13) for each q .

When the temperature approaches the critical temperature [in Fig. 6, $T_c = 0.15J$ (upper panel) and $T_c = 0.12J$ (lower panel)], the speed of sound increases. This effect arises from the temperature dependence of the gap Δ , which falls to zero when $T \rightarrow T_c$.

In Fig. 7, we plot the damping rates of the $k = 2\pi/(dN_x)$ collective mode. This is the lowest nonzero wave vector. As mentioned previously, in the FFLO state, finite damping is present already at $T = 0$ in contrast to a BCS state since the FFLO state has quasiparticle excitations even at $T = 0$.

FIG. 5. (Color online) The speed of sound parallel (c_x , circles) and perpendicular (c_y , diamonds) to the FFLO vector $\mathbf{q} = q\mathbf{e}_x$ as a function of the polarization $P = (N_1 - N_2)/(N_1 + N_2)$. Here, we vary the chemical potential difference $\delta\mu = \mu_1 - \mu_2$ to vary the polarization while holding $(\mu_1 + \mu_2)/2$ constant at $3.0J$. The other parameters for the system are $T = 0.1J$, $U = -2.8J$, and $q = 12\pi/(dN_x)$. The gap Δ is solved from the gap equation (13) for each set of parameters.

FIG. 6. (Color online) The speed of sound parallel (c_x , circles) and perpendicular (c_y , diamonds) to the FFLO vector $\mathbf{q} = q\mathbf{e}_x$ as a function of the temperature T . Here, the system parameters are, in the upper panel, $\mu_1 = 3.4J$, $\mu_2 = 2.6J$, $U = -2.8J$, and $q = 12\pi/(dN_x)$ and, in the lower panel, $\mu_1 = 3.5J$, $\mu_2 = 2.5J$, $U = -3.0J$, and $q = 12\pi/(dN_x)$. Note that the critical temperature when holding these parameters constant is $T_c = 0.15J$ (upper panel) and $T_c = 0.12J$ (lower panel).

Increasing the temperature creates more quasiparticle excitations and the damping becomes stronger. The result implies that, in a broad range of temperatures, a significant portion of the damping can be attributed to the zero-temperature quasiparticles as opposed to thermal excitations. The damping is notably enhanced close to T_c as the excitation gap Δ decreases rapidly close to T_c . The largest damping rates in Fig. 7 are 13% (upper panel) and 15% (lower panel) of the corresponding collective mode frequency, which means that the low-frequency collective modes are well defined in the entire temperature range shown.

B. Quasi-1D lattice

We now turn to quasi-1D optical lattices motivated by recent theoretical works, which predict that the FFLO state would be more stable in such geometries [38–42]. We study a

FIG. 7. (Color online) The damping rate γ of the lowest $\mathbf{k}$ mode, $k = 2\pi/(dN_x)$, in directions parallel (γ_x , circles) and perpendicular (γ_y , diamonds) to the FFLO vector $\mathbf{q} = q\mathbf{e}_x$ as a function of temperature. The parameters for the plots in the upper and lower panels are the same as in Fig. 6.

three-dimensional cubic lattice with lattice constant d and a weak hopping in two directions, i.e., $J_y = J_z \ll J_x$. The FFLO $\mathbf{q}$ vector is directed along the x axis.

In the quasi-1D setup, the collective mode spectrum along the different axes scales with the appropriate hopping strength. Therefore, one observes that $c_y/c_x \sim J_y/J_x \ll 1$. Now, it is still true that the FFLO state creates an additional difference perpendicular to the $\mathbf{q}$ vector, but the relative variation in c_y and c_z is in the same order of magnitude as in the case of an isotropic lattice and therefore negligible in comparison to the anisotropy caused directly by the hopping anisotropy. Therefore, the analysis of the sound propagation in different directions does not suggest direct means for observing the FFLO state in a single experiment in systems that are strongly anisotropic already by geometry.

However, there is another interesting feature that we find at the quasi-1D limit. In the following, we have an optical lattice with $N_L = 120^3$ lattice sites, i.e., $N_x = N_y = N_z =$

FIG. 8. (Color online) The real part of the density response function $L_{1111}(\mathbf{k}, \omega)$ for an FFLO gas in a quasi-1D optical lattice along the x axis. The hopping in the y and z directions is $J_y = J_z = 0.02J_x$ and, moreover, $\mu_1 = 2.6J_x$, $\mu_2 = 1.4J_x$, $T = 0.05J_x$, $U = -2.7J_x$, $\Delta = 0.3J_x$, and $q = 8\pi/(dN_x)$ with $\mathbf{q}$ parallel to the x axis. There are two strongly peaked responses. The lower branch corresponds to the phonon mode of the previous section, while the upper branch is caused by quasiparticle excitations centered into a narrow stripe due to the quasi-1D nature of the system.

120 lattice sites in each direction, and $J_y = J_z = 0.02J_x$. In Fig. 8, we plot the density response function $L_{1111}(\mathbf{k}, \omega)$ for an FFLO state with $\mu_1 = 2.6J_x$, $\mu_2 = 1.4J_x$, $T = 0.05J_x$, $U = -2.7J_x$, $\Delta = 0.3J_x$, and $q = 8\pi/(dN_x)$. We now find two strongly peaked responses. Both of these branches are linear for small wave vectors and also gapless. Moreover, the higher branch vanishes for $kd \approx 0.5$. The lower branch corresponds to the collective density mode of a multidimensional lattice. The higher branch, in turn, is created by the FFLO quasiparticle transitions, which are illustrated in Fig. 9. This higher branch is present also in L_{1212} , but with the opposite sign. Therefore, it tends to cancel, although not exactly, the contribution of L_{1111} in $\chi_1 = L_{1111} + L_{1212}$. To illustrate the effect clearly, we thus plot in this section L_{1111} .

In the quasi-1D limit, the quasiparticle energies are dominated by the k_x wave vector and the transverse momentum only creates a relative variation on the order of J_y/J_x to these energies. This 1D-like dispersion of the quasiparticles places a notable restriction to the possible energy and momentum transfers for small energies and momenta. On the other hand, each possible quasiparticle transition gains a significant weight for the very same reason by the following argument. Let $\delta E_0(k_x)$ be the energy of transition between an empty and a filled quasiparticle state with no transverse momentum. This means that there are filled and empty quasiparticle states at energies $E_{\pm}(k_x + p_x, p_y = 0, p_z = 0)$ and $E_{\pm}(p_x, p_y = 0, p_z = 0)$ for which $\delta E_0(k_x) = E_{\pm}(k_x + p_x, 0, 0) - E_{\pm}(p_x, 0, 0)$. Denoting then $\delta E(k_x) = E_{\pm}(k_x + p_x, p_y, p_z) - E_{\pm}(p_x, p_y, p_z)$, we find after some straightforward algebra that $\delta E(k_x) - \delta E_0(k_x) \sim J_y k_x d$, for small k_x . In other words, all the quasiparticles with different momenta p_y and p_z but the same momentum p_x contribute at a narrow energy interval on the order of $J_y k_x d$ and, therefore, we find a strongly peaked response in Fig. 8

FIG. 9. (Color online) The zero-temperature quasiparticle channels (for quasiparticles with zero transverse momentum) calculated for the system of Fig. 8. A cross denotes a transition of a single quasiparticle and a plus denotes a pair breaking, which involves the creation of two quasiparticles. At low wave vectors, there is only a narrow stripe of quasiparticle channels, which become clearly visible also in the GRPA response.

following the quasiparticle energies of Fig. 9. The strong quasiparticle response vanishes toward higher wave vectors as the quasiparticle transitions are spread to a wide energy range. Moreover, for low wave vectors, the dispersion of the lower collective mode does not overlap with the quasiparticle excitations and, therefore, the mode is undamped, unlike in the higher-dimensional case.

To compare to the results of [22] for a strict 1D system and a Larkin-Ovchinnikov (LO) ansatz (cosine form order parameter), it is interesting to notice that such a system has a similar two-mode structure at low wavelengths as the Fulde-Ferrell (FF) ansatz (plane-wave order parameter) in a quasi-1D setup. However, at higher wavelengths, the mode associated with the excess quasiparticles does not exhibit an additional Brillouin zone structure in the FF case. The reason is that this Brillouin zone structure is caused in the LO case by the oscillatory structure of the quasiparticle density profile [22], while the FF quasiparticle density profile is uniform.

V. CONCLUSIONS

We have studied the density response of a spin-imbalanced ultracold Fermi gas in an optical lattice in the FFLO state. By using the Kadanoff-Baym formalism, we derived the linear response function for this system in the generalized random-phase approximation. We then calculated the collective mode spectrum in a 2D square optical lattice and showed that the speed of sound is anisotropic due to the anisotropy of the FFLO pairing. This suggests an experiment in which one monitors the propagation of a local density perturbation in order to find evidence of the anisotropic pairing mechanism of the FFLO state.

Moreover, we studied the damping of the collective modes and showed that, despite the presence of quasiparticles in the FFLO ground state, the collective modes have a relatively weak damping rate and are thus well defined and physically meaningful elementary excitations of the system.

We also studied a quasi-1D system. In this case, the anisotropy of the sound propagation is predominantly caused by the anisotropy of the lattice itself in contrast to a possible exotic pairing mechanism. However, the quasi-1D system is qualitatively different from higher-dimensional systems as it contains an additional collective-type response of quasiparticles.

To draw future guidelines, a clear way to improve on the results presented in this paper would be the inclusion of more elaborate order-parameter structure, in particular, the LO ansatz with a cosine-type order parameter. In this case, one can not simplify the problem in momentum space to the same extent as in Sec. III B of this paper, and a heavier numerical method in position space is called upon. One would still anticipate an anisotropic speed of sound for the LO ansatz as well, based on presenting the state as a superposition of two FF states, as well as by the arguments of [29].
